Bibliographic references, to be useful, should include only such as have a direct reference to the subject in hand, and which bring out or elucidate some point of interest. It is only in the case of little known or new disorders or operations that anything like an exhaustive bibliography should be attempted. In that case a conscientious student of the subject does not feel particularly thankful to find a bibliography including matter that has only a distant relation to the subject which he is investigating. Many authors, in their desire to be comprehensive, have been guilty of this error. With subjects having an extensive literature an ill-selected, possibly inaccurate, list of references to a small number of papers, such as we sometimes see, even in text-books, is not only useless, but a nuisance. The only use for a bibliography of any subject is to give the reader a fair general, if not an actually exhaustive, view of the really important literature. Each reference should be to some real contribution to our knowledge, not to an uncritical rehash of facts already known. If abstracts are quoted, they should be quoted as such and not as original references. It would be better also if the full title of each article referred to were given, as well as the name of the author and the periodical, date of issue, year, volume and page. In that case the reader would have a better chance to know whether or not the reference was one that would be of interest to him. This would, of course, require a little more industry on the part of the compiler.

The *Index Medicus* and the Index-Catalogue of the Surgeon-General's Library have been a great boon to the medical profession, but, like other good things, they are capable of misuse. While the worst offenders in this matter of fake or semi-fake bibliography are those who copy without scruple from others, who may themselves be only second-hand copyists of still others, there is a probably much larger class of men who do not hesitate to do much of their reference work directly from the two above publications. This is neither entirely honest nor altogether safe. Even the full references given can not always convey a correct idea of the value of the articles listed, and no attempt to do so is made by the compilers. No reader cares much for a bibliography which, without pretending to be exhaustive, indiscriminately includes the worthless and the good, together with the duplicated publication of articles with which some writers cumber the record, practically recommending all alike as worthy of study. It is an imposition on the honest student to offer such a list of references.

It is not intended in these remarks to imply that the great mass of the bibliographic work in American medical literature is not honestly and judiciously done. The evidence, we believe, is decidedly to the contrary. Nor would we have it inferred that some of the faults we have here noticed are due to intentional dishonesty. There is a sort of carelessness sometimes in such work that can hardly be called by so harsh a name; nevertheless it is not commendable, and so far as the tendency exists it calls for condemnation. There is a temptation to sciolism among a certain class of workers in every department of human knowledge, and some medical writers capable of doing better work are guilty of it through indolence and thoughtlessness if nothing worse. As some one has said, in medical writings, above all others, absolute sincerity is the one indispensable virtue. Until that virtue has been attained there will be room for amendment.

THE ADVANCE AND RETREAT OF MEDICAL STANDARDS.

It is often assumed that practical advances, once secured, will be easily maintained, and, indeed, that the law of progress is practically automatic and irreversible in its workings. That this is not true may be readily appreciated from two half-forgotten chapters in medical history recently recalled to the mind of the medical profession of to-day.

The law of Frederick II of Germany, for the regulation of the practice of medicine[1]—which is, so far as known, the earliest modern law on that subject—proves that before the middle of the thirteenth century many recently secured or perhaps still unattained improvements in the regulation of medical practice had been anticipated on the statute-books of the Two Sicilies. Four years of medical study, three years of preliminary education, a year with a physician before regular practice might begin—all this was required for the honor and dignity of the medical profession nearly seven centuries ago. At the same time many abuses in the relations of physicians and druggists were regulated, and the purity of drugs was secured by enactment.

An article on the first American medical school by Dr. James J. Walsh[2] shows that, though we have been usually accustomed to say that the first lectures in medicine in America were given at the University of Pennsylvania in 1765, this event was anticipated by almost two centuries at the University of Mexico, where the first lectures in medicine were delivered about 1580. A complete medical school was established in connection with this university in the early part of the seventeenth century. At this medical school four years of attendance at lectures were required for graduation and three years of preliminary study before the student was allowed to enter the practice of medicine. The medical course of the Mexican medical school was founded mainly on Hippocrates, though Galen and Rhazes were also faithfully studied. The diploma of graduation from this medical school was required for practice in the important towns of Mexico. There are a number of interesting remains of this work. The first medical book ever written in America, entitled "Secretos de chirurgia," was by Dr. Pedrarias de Benavides and was published at Valladolid, Spain, in 1567. The first medical book ever published in this country was "Opera Medicinalia" by Francisco Bravo, copies of which are probably to be found in old Mexican book stores and perhaps also in Spanish collections. This would be a rare medical bibliographic treasure for American medical libraries.

[1] The Journal, Feb. 1, 1908, p. 388.

[2] New York Med. Jour., Oct. 10, 1908

These two epoch-marking medical achievements have been all but forgotten; the dreary decadence that followed each is only too familiar to the student of medical history. A strange and melancholy phenomenon it seems that the advances in social and professional conditions attained by the prolonged and serious efforts of former generations should have been allowed to slip from the nerveless grasp of those succeeding. Therefore, these records of the past are all the more interesting because they emphasize the necessity for continued effort to advance if we would even maintain the standards set by our predecessors. The characters deciphered from these fading palimpsests of history spell both a warning and a stern, peremptory challenge to be up and doing.

Medical men are sometimes inclined to think that this generation has accomplished enough, and that too much attention is being devoted to the uplift of the profession. Yet they, better than any others, should know that incessant effort is the price, not only of progress, but of existence itself.

CHOLERA IN RUSSIA.

Cholera in Russia, which has recently caused well-founded alarm in all countries having commercial intercourse with the infected region, is reported in the Public Health Reports to be on the decrease. The present outbreak began in July and August principally in Astrakhan and Saratov, the disease having been previously absent from Russia since last January. Its appearance in the remote southeastern provinces of Russia in July did not attract much sanitary attention. In September, however, when cases began to appear in the neighborhood of St. Petersburg, the situation was justly regarded as grave.

The cases have since increased alarmingly, not only in the Russian capital but in many other parts of the country; at St. Petersburg between 6,000 and 7,000 have been recorded, with a mortality of about one in three. On the appearance of cholera at St. Petersburg the Public Health and Marine-Hospital Service sent a medical officer to Russia with orders to report on the situation. An inspection service in the interest of the United States has since been established at Libau, on the Baltic, the only Russian port from which emigration takes place to the United States. At Libau, which is connected with St. Petersburg and other infected districts by railroad, intending emigrants are detained in close quarantine for five days. If, after this period of detention, conditions are satisfactory they are allowed to go into the city and are lodged in various places under observation until their departure. Before embarking emigrants undergo final examination and all baggage is disinfected prior to being taken on board. The voyage from Libau to New York lasts from seventeen to eighteen days. Libau has a water supply from artesian wells over 200 feet deep. The last occurrence of cholera at that place was in 1892, when all the members of one family were attacked, but the disease did not spread.

The great mass of Russian emigration is via ports of other European countries whose own interests make them exercise a vigilant surveillance of suspected travelers passing through their gates. Germany's calamitous cholera experience, beginning in 1892 with the sudden appearance of the disease in Hamburg—an important port of departure for Russian emigrants—taught a convincing lesson in regard to the relation of the water supply to cholera. An epidemic causing within ten days of its outbreak 1,000 cases a day is not soon forgotten. This outbreak lasted three years, visiting hundreds of places in that country and threatening the entire world.

At St. Petersburg many conditions exist which favor the spread of cholera when once introduced. The city, built on made ground, is surrounded by a network of stagnant canals, whose water is frequently drunk by the poorer classes. Hamburg's lesson of defiled water supply should be put to practical application at St. Petersburg.

THE RELATION OF PHYSIOLOGY TO PHYSICS AND CHEMISTRY.

Compared with the utterances of one of his predecessors, it is noteworthy that Dr. J. S. Haldane,[1] in his opening address as president of the physiologic section of the British Association for the Advancement of Science, places himself without reserve among the, as he believes, increasing number of physiologists who are not satisfied with physico-chemical explanations of all physiologic facts. It seems to him, he says, *that* while the advance in physiology appears to have brought us in some ways nearer to a physico-chemical explanation of life, it has in other ways put us further off. On the one hand we are accumulating facts as to the physical and chemical source and ultimate destiny of the matter and energy passing through the animal body; on the other hand there is an equally rapidly accumulating knowledge of an apparent teleologic ordering of this material and energy which is beyond our present ability to account for by chemical and physical laws. The time is past, he says, when we can shut our eyes to this knowledge, and we must face again the old problem of life. In physiology, and in biology generally, he holds that we are dealing with facts which, so far as our present knowledge goes, differ not only in complexity but also in kind from physical and chemical phenomena. In particular he points out how impossible it is to account for all the facts of reproduction and heredity from a purely mechanistic standpoint. The difficulty does not exist if we use the conception of a living organism with its specific activities and bearing the same relation to biology as matter and energy do to physics or the atom or ion to chemistry. Berkeley, Hume and others have shown that the fundamental hypotheses of physical science are only of value so far as they successfully fulfill their purposes. We are justified, therefore, in seeking for a conception of life that will serve better as a working hypothesis than the physico-chemical one. As regards the charge that will be made "that the change of front" here urged "involves the giving up of all real attempt at scientific explanation in biology," he says that, leaving aside the philosophical question involved, the first requisite of a working hypothesis is that it should work, and he has tried to point out that the physico-chemical theory of life has not worked in the past, and it is his belief that it never can work. "As soon as we pass beyond the most superficial details of physiological activity it becomes unsatisfactory, and it breaks down completely when applied to fundamental physiologic problems such as that of reproduction." It is perhaps significant in this connection that the opening address before the botanical section by its president, F. F. Blackman,[1] while devoted to the manifestations of the principles of chemical mechanics in plants, almost starts out with the statement that the question "whether there is not here some discontinuity in Nature; whether the play of molecular and atomic forces occurring outside the living organism can ever account for the whole of the complexity and correlation of chemical and physical interactions demonstrable within the living structure," is very far from being answered, and that in a scientific assembly no one will call for prophecies. This is very different from and, it appears to us, more scientific than the dogmatic assumptions of the identity of vital and physico-chemical processes or the condemnation of any contrary views as detrimental to scientific progress. The "specter" of vitalism, as Dubois-Reymond called it, is still before us and it seems at times a pretty healthy ghost.

[1] Nature, October 1.

HOPEFUL PROGNOSIS.

"To those who see much of this (locomotor ataxia) and like diseases it is a patent fact that there is always a liability to suggestion which seems almost characteristic and inseparable from the condition of invalidism." This is one of the opening sentences in Dr. Hamilton's paper printed in this issue.[1] The powerful influence exerted by the mental state over the ordinary physiologic processes of the body is well known. Fear may dry up the saliva, check the flow of the digestive juices, paralyze the sphincters and cause failure of the heart's action. Worry retards or perverts the processes of digestion and assimilation, inhibiting digestive secretions and even reversing peristaltic action. On the other hand, appetizing sights and odors induce a mental state that stimulates the digestive juices. Digestion is promoted by cheerfulness and placidity. It is alleged that death has occurred from a determination to die and from a (unfounded) belief that it was inevitable, in conditions in which no adequate cause of death was discoverable, either clinically or at postmortem examination. It is well known that in a certain percentage of cases spontaneous recovery, or at least recession, occurs, not only in locomotor ataxia but in tuberculosis, asthma and other diseases ordinarily regarded as incurable. Fear undoubtedly exercises a depressing influence, and, *per contra*, hope and encouragement stimulate and refresh. There is more than imagination in the often heard remark, "It does me good even to see the doctor; his presence brings confidence and hope." Contrariwise, the depressing effect of an over grave demeanor, and especially of a grave prognosis uttered in a patient's hearing, or even in his sight, can hardly be overestimated in its effect on his natural defensive forces, which ought to be keyed by the physician up to concert pitch. The moral is that an unfavorable prognosis should be given only with extreme caution, and then seldom absolutely, but accompanied with the encouragement that even the most forlorn hopes have at times succeeded. The patient should always be given the benefit of all hope and encouragement that is possible. If a hopeless prognosis is felt to be inevitable it should be given usually to the friends rather than to the patient. The failure to observe this admirable caution leads to two serious evils. First, it undoubtedly, in many cases, proves the final straw that breaks down the struggle for recovery. Second, the prognosis sometimes misses after all; and then if the patient falls into the hands of some irregular practitioner, faith healer or whatnot—who, whatever else he does, is sure to make the most of this element in treatment — the result may be another vaunted case of "recovery from a fatal disease after all the doctors have given him up."

Medical News

CALIFORNIA.

County Society Investigates Use of Proprietaries.—The San Joaquin County Medical Society has sent a circular letter to its members announcing the appointment of a special committee to look into the abuses arising from the use of proprietary medicines. The results on the physicians *prescribing* such preparations are summarized as follows:

1. The physician becomes lazy as far as prescribing National Formulary preparations is concerned.
2. He compels the druggist to load his shelves with a lot of medicines easily compounded by any intelligent pharmacist.
3. The druggist, having these preparations on his shelves, is tempted to prescribe for many people who would otherwise consult a physician.
4. Any intelligent person, reading the prescription which the doctor writes before presenting it to the druggist, becomes familiar with the name of the preparation and thereafter buys it in the original package.
5. The doctor, in his efforts to dispose of these preparations, becomes an agent for proprietary medicine concerns.

This subject was taken up with a number of pharmacists in San Joaquin County, who stated that they were anxious to assist the physicians in this movement so as to eliminate a large number of proprietary preparations which they were compelled to carry. A sheet containing twenty questions was sent to each member of the society. Some of these questions are:.

Can you with your present knowledge of pharmacy write a prescription containing anything you desire? If so, why don't you?

When you prescribe proprietary preparations, do you remember all the ingredients they contain?

Is it not the physician's fault that proprietary remedies are kept in stock in all drug stores?

Does not a physician's knowledge of therapeutics become less after using proprietary medicines for ten or twenty years?

Do you honestly believe that you cure more patients by using proprietary medicines than by using separate drugs? Why do you use them?

A summary of the answers received in reply to these questions would certainly be interesting.

ILLINOIS.

Medicine Man Fined.—H. Darwin McIlrath, president of a medicine company in Chicago, charged with practicing medicine without a license and prosecuted by the state board of health, is said to have been found guilty November 16 and fined $100.

Subnormal Children to Be Segregated.—Plans announced by the president of the Board of Education of Chicago are to the effect that tubercular and subnormal children in the public schools of Chicago are to be segregated and provided with a special mental and physical training institute to be founded on a 240-acre tract of land in Riverside. Arrangements are also being made to provide a substitute for the present John Worthy School for delinquent children on the same tract of land.

Chicago.

Deaths of the Week.—For the week ended November 28, 520 deaths were reported to the Department of Health, 76 fewer than for the preceding week and 18 in excess of the corresponding week of last year. Consumption caused 63 deaths; pneumonia, 61; heart diseases, 49; acute intestinal diseases, 42; violence (including suicide), 34; scarlet fever, 13; diphtheria, 9; typhoid fever, 8; measles, 4, and whooping cough, one death.

Contagious Diseases.—There were 968 cases of contagious diseases reported to the department during the week ended November 28, distributed as follows: Scarlet fever, 255; diphtheria, 222; tuberculosis, 189; chickenpox, 90; typhoid fever, 44; pneumonia, 31; whooping cough, 18, and minor contagious diseases, 25. Compared with the preceding week, the cases of diphtheria increased 7, but the deaths from this cause decreased 14. There were 43 more cases of scarlet fever, but the number of deaths remained the same.

MAINE.

Medical School Opens.—The Medical School of Maine, Brunswick, reopened after its summer vacation, October 23.

Personal.—Dr. Charles E. Williams, Auburn, was seriously injured by the overturning of his automobile in Leeds, October 9, while on his way to his summer camp on Androscoggin Lake. Mrs. Williams died from the injuries received.——Dr. William P. Hutchins, Rumford, was held up and robbed of $250 recently.——Dr. Eben J. Marston, Bath, while making a professional call, was attacked and bitten in the face by a collie dog. The wounds were cauterized at once and no ill effects are anticipated.

Embargo on New Brunswick Immigration.—The secretary of the State Board of Health has received information from the inspector of the board near Madawaska that there are 125 cases of smallpox in the town of Edmonston, N. B. Letters of warning have been sent to local boards of health in the western part of the state, ordering that until further notice no person shall go from the province of New Brunswick into Maine, unless he can prove to the satisfaction of the local board of health that he has been vaccinated and that he has not been exposed to smallpox.

Society Meetings.—The fifty-fifth annual meeting of Penobscot County Medical Society was held November 17, in Bangor. The following officers were elected: President, Dr. Harry Butler; vice-presidents, Drs. J. Albert Lethiecq, Brewer, and Herbert T. Clough, Bangor; secretary, Dr. John B. Thompson, Bangor, and treasurer, Dr. Harold H. Crane, Bangor.——At the annual meeting of Androscoggin County Medical Association, resolutions were adopted urging the establishment by the government of a national department of public health.——At the annual meeting of the Westbrook Medical Club, the following officers were elected: President, Dr. Alphonso N. Witham; vice-president, Dr. Adjutor Coutourier; and secretary-treasurer, Dr. Louis L. Hills.——At the annual meeting of the Cumberland County Medical Society, held in Portland, the following officers were elected: President, Dr. Owen P. Smith; vice-president, Dr. Herbert F. Twitchell; secretary, Dr. Harold A. Pingree; treasurer, Dr. Edwin W. Gehring; and censors, Drs. Stanley P. Warren, Charles W. Foster and Frank H. Jordan, all of Portland.

MARYLAND.

Medical Club Organized.—An association of physicians of Washington County, known as the Medical Club, was organized at Hagerstown, November 25, the object being the promotion of scientific progress and good fellowship.

Personal.—Dr. W. Frank Hines, superintendent of state immigration, has moved from Chestertown to Baltimore.——Dr. R. Owens, mayor of Hyattsville, and treasurer of the Maryland Agricultural College, is under treatment at Johns Hopkins Hospital.

State Under Quarantine.—The State of Maryland has been placed under quarantine by the Secretary of Agriculture on account of an epidemic of foot-and-mouth disease among cattle at Lineboro. The infection is said to have been introduced by cattle sent from Buffalo.

Baltimore.

Gift to Dispensary.—An anonymous benefactor has given $15,000 to build an addition to the Phipps Dispensary of Johns Hopkins Hospital. This will practically double the capacity of the institution.

Isolation Hospital Nearing Completion.—Sydenham Hospital for Infectious Diseases is almost completed and will be opened January 1. Dr. W. B. Morrill of the Children's Hospital, Detroit, has been appointed physician in charge, and began his duties December 1.

Eminent Scientist Dies.—Prof. William Keith Brooks, a member of the faculty of Johns Hopkins University since its foundation, died in Baltimore, November 12, aged 60. He was distinguished as a biologist and was known as the "Father of the Oyster Culture."

Portrait Presented.—At the meeting of Baltimore Medical Society, December 1, the subject of "Proprietary Medicines" was discussed, and a portrait of the late Dr. George J. Preston was presented to the Medical and Chirurgical Faculty of Maryland by his friend, Dr. Harry Friedenwald.

City Alms House Condemned.—The grand jury, in its report, characterizes the condition of Bayview Asylum, the city alms house, as "frightful," recommends an appropriation for the erection of a building for hospital purposes only, and that arrangements be made with the state whereby the hopelessly insane may be cared for in the state institutions.

Personal.—Dr. Albert H. Carroll has returned from Brazil.——Dr. Thomas McC. Anderson sailed for Bremen, November 11.——Dr. Charles G. Hill has been elected president of the North Carolina Society of Maryland.——Dr. Roland B. Whitridge has returned from Europe.——Dr. Gladys R. Henry, the only woman resident physician at Johns Hopkins Hospital, was operated on for appendicitis, November 17.——Dr. Theodore Cooke, Jr., was elected president of the Association of Prison Physicians and Surgeons at Richmond, November 18.——Dr. Hugh H. Young, Johns Hopkins Hospital, while returning from a hunting expedition, fell and fractured his left arm——Dr. Owen C. Smith, professor of pharmacy in Baltimore Medical College, had his left eye enucleated November 23, as the result of an injury received while hunting six days before.

MICHIGAN.

Society Meetings.—At the annual meeting of Eaton County Medical Society, held in Charlotte, October 29, Dr. Arthur R. Stealy, Charlotte, was elected president; Dr. Wallace Newark, Charlotte, vice-president; Dr. Arthur H. Burleson, Olivet, secretary-treasurer; Dr. Philip H. Quick, Olivet, delegate to the state society; and Dr. Charles A. Stinson, Eaton Rapids, alternate. At the annual meeting of Ingham County Medical Society, held in Lansing November 12, Dr. Oscar H. Bruegel, Agricultural College, was elected president, and Dr. Charles H. Brucker, Lansing, vice-president, and Dr. Samuel Osborn, Lansing, was re-elected secretary-treasurer.——The Detroit Society of Neurology and Psychiatry was organized at the Detroit Club, November 19, with thirty charter members. The society is to meet four times a year and devote its energies to the study of neurologic and psychiatric problems. The following officers were elected: President, Dr. Colonel B. Burr, Flint; vice-president, Dr. David Inglis, Detroit, and secretary-treasurer, Dr. Charles W. Hitchcock, Detroit, and these officers, with Drs. Albert M. Barrett, Ann Arbor, and Edmund A. Christian, Pontiac, form the council.

MISSOURI.

Ask a Quarter Million.—The Hospital and Health Board, Kansas City, at a meeting November 18, adopted a recommendation to the council to submit a proposition to vote bonds to the amount of $250.000 for an incineration plant and $20,000 for a municipal tuberculosis sanatorium at Leeds.

Convicted and Fined.—H. M. Blumenthal, a traveling eye specialist, who has been fitting glasses, treating eyes, etc., is said to have been fined $100 at Nevada, Mo., for violating the statutes governing the practice of medicine without a license. Other cases against this individual are likely to be pushed as the medical profession of Nevada is determined to break up the illegal practice of medicine in that place.

County Medical Society Elects.—Ray County Medical Association held its annual meeting in Richmond, October 31, and elected the following officers: Dr. Elmer T. McGaugh, Richmond, president; Dr. Robert Sevier, Richmond, vice-president; Dr. Herman S. Majors, Hardin, secretary; Dr. Edward F. Higdon, Richmond, treasurer; Drs. Emmet W. Rentfro, Rayville; George W. Joiner, Knoxville, and James E. Ball, Millville, censors; Dr. Herman S. Majors, delegate to the state medical society, and Dr. James W. Smith, Richmond, alternate.

St. Louis.

Add to Consulting Staff.—At the last meeting of the consulting staff of St. Louis Maternity Hospital, the following additions were made: Dr. William W. Graves, neurologist; and Dr. Abram C. Leggatt, surgeon.

Medical Aid in Schools.—Emergency cabinets are being placed in the public schools in St. Louis under the auspices of Dr. James Stuart, supervisor of schools, to enable the superintendents to render first aid in emergencies.

Meningitis Serum.—A supply of Flexner serum has been placed in the hands of Dr. Harris, city bacteriologist, and Dr. McConnell, pathologist of the Skin and Cancer Hospital, who will distribute it to physicians requiring it for use in cases of meningitis.

Object to Cancer Hospital.—Residents of the neighborhood of Forest Park Boulevard object to the new Barnard Free Skin and Cancer Hospital on that thoroughfare, and threaten to resort to law. The land for the building and $100,000 for the endowment of the institution were donated by Mr. George T. Barnard.

Free Beds in Hospital.—The board of directors of the St. Louis Protestant Hospital has recently determined to open the entire institution wards and rooms to patients who require special treatment but who are unable to pay both hospital and physicians' fees. Such patients will be admitted only on written recommendation of a physician, and will receive medical and surgical treatment in the institution free of charge.

NEW HAMPSHIRE.

Anniversary Reception.—The Nashua Medical Association, on October 16, gave a reception to Dr. and Mrs. Charles B. Hammond, in honor of the twenty-fifth anniversary of their marriage. Dr. Ella B. Atherton, in behalf of the association, presented Dr. and Mrs. Hammond with a silver candelabrum.

Society Meetings.—At the annual meeting of the Rockingham County Medical Association, held in Portsmouth November 12, the following officers were elected: President, Dr. Abram W. Mitchell, Epping; vice-president, Dr. William O. Junkins, Portsmouth; secretary, Dr. Walter Tuttle, Exeter; treasurer, Dr. Alice M. Chesley, Exeter; delegates to the state society, Drs. John W. Parsons, Portsmouth, and George H. Guptill, Raymond; and censors, Drs. William H. Nute, Exeter, and Fred S. Towle, Portsmouth.——At the centennial meeting of Stratford County Medical Society, held in Dover October 29, Dr. Lewis W. Flanders, Dover, was elected president; Dr. Thomas J. Dougherty, Somersworth, vice-president; Dr. Harry O. Chesley, Dover, secretary; Dr. A. Noel Smith, Dover, treasurer; Dr. Micah B. Sullivan, Dover, auditor: Dr. George P. Morgan, Dover, censor; and Dr. Charles C. Rogers, Farmington, delegate to the state society.

NEW JERSEY.

Prevention of River Pollution.—The municipalities of Camden and Riverton have received notice from the State Board of Health that they must stop the practice of discharging crude sewage into the Delaware River, and that before Sept. 1, 1913, they must install sewage disposal plants and have them in full operation.

October Vital Statistics.—During the month ended October 15, 2,904 deaths were reported to the Bureau of Vital Statistics. Of these, 786 were of infants under 1 year, 261 were of children from 1 to 5 years, and 782 of individuals 60 years old and over. Among the principal death causes were: Infantile diarrhea, 367; diseases of the nervous system, 351; diseases of the circulatory system, 307; tuberculosis, 298; nephritis, 194; cancer, 144; pneumonia, 125; diphtheria and typhoid fever, each 34; cerebrospinal meningitis, 24; whooping cough, 21; scarlet fever, 18; and measles, 1.

Personal.—Dr. Paul N. Litchfield, Camden, has been elected coroner of Camden County, vice Dr. Joel W. Fithian.——By the will of Mr. Walter Ammon, who was shot and killed in Jersey City recently, one-third of his interest in the Ammon Butter and Egg Company were devised to Dr. John J. Baumann, Mr. Ammon's physician and most intimate friend.——Dr. J. Watson Martindale, Camden, was thrown from his carriage, November 20, and sustained a fracture of the scapula.——Dr. William K. Newton has been elected president, Dr. George E. Tuers, vice-president; Dr. Joseph A. Maclay, secretary, and Dr. Archibald F. Anderson, treasurer of the medical board of Paterson General Hospital.——Dr. P. DuBois, Bunting, was elected president; Dr. Frederick H. Pierson, vice-president; Dr. Russel A. Shirrefs, secretary, and Dr. John H. P. Conover, treasurer, of the Medical Society of the Elizabeth General Hospital and Dispensary, at the fifteenth annual election.

NEW YORK.

Mortality Among Bottle-Fed Babies.—The current bulletin of the State Health Department shows that during 1907 there were 37,370 deaths of infants under 2 years of age in the state. Investigators place the proportion of deaths between bottle-fed and breast-fed babies as 25 to 1, and this would give 8,844 deaths from this cause among bottle-fed babies last year, a greater number than was claimed by all other infectious and contagious diseases, excepting tuberculosis, combined.

Election.—At the one hundred and third annual meeting of the Medical Society of the County of New York, held November 23, the following officers were elected: President, Dr. H. Seymour Houghton; vice-presidents, Drs. John E. Weeks and Joseph Brettauer; secretary, Dr. John Van Doren Young; assistant secretary, Dr. J. Milton Mabbott; treasurer, Dr. Charles H. Richardson; censors, Drs. J. Riddle Goffe, Henry M. Painter, Charles G. Kerley and Albert W. Ferris; delegates to the Medical Society of the State of New York. Drs. H. Seymour Houghton, Floyd M. Crandall, W. Bryant Hoag, E. Eliot Harris, Henry M. Silver, J. Milton Mabbott, Abraham Jacobi, Michael C. O'Brien, Egbert Le Fevre, Frederic R. Sturgis, Arnold Knapp, Frank S. Fielder, Walter L. Carr, Charles H. Richardson, John A. Bodine, Edward M. Foote and Edmund P. Fowler.

Meeting of Medical Examiners.—The State Board of Medical Examiners, at its meeting November 15, elected Dr. William Warren Potter, Buffalo, president, and Dr. William S. Searle, Brooklyn, vice-president. It placed itself on record as being in favor of the six-year combined baccalaureate and medical course. Arrangements were made for the preparation of a medical syllabus in keeping with the suggestion of prominent medical educators, and a committee, of which Dr. Lee H. Smith, Buffalo, is chairman, was continued. The assignments to the various subheads of medicine were voted as follows: Physiology, Dr. R. H. Williams, Rochester; anatomy, Dr. William S. Ely, Rochester; hygiene and sanitation, Dr. Eugene Beach, Gloversville; chemistry, Dr. Floyd S. Farnsworth, Plattsburg; surgery, Dr. Floyd M. Crandall, New York; obstetrics and gynecology, Dr. William W. Potter, Buffalo; bacteriology, Dr. Frank W. Adriance, Elmira; pathology, Dr. Lee H. Smith, Buffalo; and diagnosis, Dr. William S. Searle, Brooklyn. The following were elected members of the question committee: Drs. Smith, Potter, Adriance and Williams.

New York City.

Death of Dr. McCosh.—Dr. Andrew J. McCosh, who was injured November 28, in a runaway accident, suffering a fracture of the base of the skull and other injuries, died in the Presbyterian Hospital, December 2.

Tuberculosis Exhibit.—The international tuberculosis exhibit will be open free to the public for six weeks at the American Museum of Natural History, Seventy-ninth Street and Columbus Avenue, beginning November 30.

Harvey Society Lecture.—The fifth lecture of the Harvey Society by Drs. M. J. Rosenau and John F. Anderson, P. H. and M.-H. Service, on December 5, at the New York Academy of Medicine, is on the subject of "Anaphylaxis."

Campaign Against Tuberculosis.—Under the auspices of the section of public health of the New York Academy of Medicine, a special meeting will be held December 11, at which Prof. Walter F. Wilcox of Cornell University will deliver an address on "The Need of New York State for Better Vital Statistics in Its Campaign Against Tuberculosis."

Joint Meeting.—On December 9, joint meeting of the New York Pathological Society and the New York Surgical Society will be held, at which a paper by Drs. John Howland and A. N. Richards will be presented on "Experimental Study of Pathology and Metabolism in Delayed Chloroform Poisoning." The subject will also be discussed from the clinical standpoint.

Shall Presbyterian Hospital Move?—The Presbyterian Hospital is fast outgrowing its present accommodations at Seventy-first Street and Park Avenue, and, as more hospital facilities are needed in the tenement district to the east, real estate experts are urging the trustees to sell their present property and to buy a new site in the forenamed district while real estate is still comparatively cheap.

New Hospital Opened.—The Mount Moriah Hospital, a nonsectarian institution on the East Side, has just been opened. Edward Lauterbach, who made the opening address, deplored the fact that the hospital charter had not been granted by the State Board of Charities, and has pledged himself to endeavor to obtain a charter from this organization. The money for this hospital was raised by private subscription, the largest contribution being limited to $250. There is a guarantee fund to meet all expenses for five years. There is an equipment of 80 beds, an operating room, and a children's ward.

NORTH CAROLINA.

Pasteur Institute Report.—On July 1, the State Board of Health established a Pasteur institute in Raleigh. During the first four months of its existence 34 patients were treated, all but eight of whom were free patients.

Hospital Notes.—The Gaston County Hospital, Gastonia, was formally opened November 12.——On October 30 and 31, tag days were held in High Point for the benefit of the Junior Order Hospital of that city.——The floral bazar held by the ladies of Charlotte the first week in November netted a little over $500 to St. Peter's Hospital in that city.

OHIO.

Hospital Notes.—St. Clair Hospital, Cleveland, has purchased 90 feet of land adjoining its present location for $8,000 and proposes to erect a new building on this site.——The new Jefferson Hospital, Toledo, was formally opened, November 11, with a free clinic and a banquet to the staff.

District Society Meetings.—The fifth annual meeting of the First District Medical Society was held in Cincinnati November 16. Dr. Hugh J. Death, Franklin, was elected president; Dr. John C. Larkin, Hillsboro, vice-president, and Dr. John P. Miller, Cincinnati, secretary.——At the annual meeting of the Second District Medical Society, held in Troy November 12, Dr. J. Emerson Monger, Gettysburg, was elected president; Dr. Ralph A. Bunn, Dayton, vice-president, and Dr. Asa C. Messenger, Xenia, secretary (re-elected).——The Ninth District Medical Society held its sixth annual meeting in Toledo November 10 and elected Dr. Peter J. Kline, Portsmouth, president; Dr. Jehu Eakins, Gallipolis, censor; Dr. Joseph S. Rardin. Portsmouth. secretary. and Dr. John E. Sylvester, Wellston, councillor, the two latter being re-elected.

PENNSYLVANIA.

Loss by Fire.—The two-story annex of the Idlewood Sanatorium in Greentree Borough was destroyed by fire November 9. The loss is estimated at $10,000.——The new Tuberculosis Camp for Women at Marshalsea was burned to the ground November 5, involving a loss of about $6,000, partially covered by insurance.

New State Institution.—The Eastern Pennsylvania State Institution for the Feeble-Minded and Epileptics, Spring City, was formally opened November 16. Six buildings are already completed at a cost of $350,000. For the time being the institution will admit only men, but when entirely completed, 23 buildings will be erected at a total contemplated cost of more than $1,000,000, making this one of the best equipped institutions of its kind in the world.

Officers Elected.—At the annual meeting of the Somerset County Medical Society held at the Markleton Sanatorium, the following officers were elected for the coming year: President, Dr. Charles P. Large, Meyersdale; vice-president, Dr. Richard T. Pollard, Garrett; secretary, Dr. Bruce Lichty, Meyersdale; treasurer, Dr. Walter S. Mountain, Confluence; reporter, Dr. Henry C. McKinley, Meyersdale; county censors, Drs. Henry Wilson, Somerset, Albert M. Lichty, Elk Lick, and Ross J. Hemminger, Meyersdale; and district censor, Dr. Henry I. Marsden, Somerset.

The Cattle Plague.—The epidemic of foot and mouth disease continues to spread throughout the state, and 12 counties are reported to have been placed under federal and state quarantine. The counties quarantined are: Montour, Northumberland, Juniata, Union, Snider, Lehigh, Lancaster, Berks, Delaware, Montgomery, Crawford and Lebanon. More than 1,000 cattle have been killed in an effort to prevent the spread of the disease. The care of the epidemic is under the supervision of Dr. Leonard Pearson and Dr. Mohler of the state and government service. The disease has been reported to have been communicated to the adjoining states, New York and New Jersey.

Philadelphia.

Anonymous Gift.—The Hospital of the Woman's Medical College of Pennsylvania has recently received an anonymous gift of $500 for its endowment fund.

Beneficiaries of Charity Ball.—The receipts of the twenty-ninth annual charity ball, to be held in the Academy of Music, January 27 next, will go to the following beneficiaries: Children's Orthopedic Ward of the University Hospital, Children's Ward of the Jefferson Hospital, Kensington Hospital for Women and St. Christopher's Hospital.

Society Meeting.—At the annual meeting of the Pathological Society of Philadelphia, held October 22, the following officers were elected: President, Dr. Joseph McFarland; vice-presidents, Drs. David L. Edsall, Reisman, Kelly and Smith; secretary, Dr. Ralph S. Lavenson; treasurer, Dr. Courtland Y. White; recorder, Dr. Frederick H. Klaer; and curator, Dr. E. H. Goodman.

Campaign for Health.—A public meeting of the Philadelphia Society for the Prevention of Diseases was held in the hall of the College of Physicians November 6. The officers of the society are Dr. Edgar F. Smith, president; Dr. William W. Keen, Charles C. Harrison, LL.D., and Col. R. Dale Benson, vice-presidents; Dr. Robert N. Willson, secretary; and Dr. Jay F. Schamberg, treasurer.

Health Report.—The total number of deaths reported to the Health Bureau for the week ended November 21 was 420. This is a decrease of 33 from the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 3; pertussis, 2; diphtheria, 6; consumption, 59; cancer, 18; diabetes, 3; apoplexy, 11; paralysis, 6; heart disease, 53; acute respiratory disease, 51; enteritis, 23; hepatic cirrhosis, 3; appendicitis, 5; nephritis, 44; premature birth, 12; congenital debility, 7; senility, 3; suicide, 4; accidents, 15, and marasmus, 7. There were 201 cases of contagious diseases reported, with 12 deaths, as compared with 215 cases and 32 deaths reported in the preceding week.

Personal.—Dr. Robert-Simon, Paris, delivered an illustrated lecture on "The Subcutaneous Injection of Sea-Water in the Treatment of Disease" in the Polyclinic Hospital November 20.——Dr. Joseph J. Walsh, professor of the history of medicine at Fordham University, delivered an address on "Old Time Medicine and Medical Education" at the regular monthly meeting of the College of Physicians, November 30.——Dr. George W. Crile, Cleveland, Ohio, has been selected to deliver the annual Mutter lecture for the College of Physicians for 1908. He will discuss "Surgical Anemia and Resuscitation." The lecture will be delivered December 11 in the Mutter Museum of the college.——Dr. Charles A. E. Codman has been appointed chairman of a committee to investigate the subject of a business bureau for the county medical society.——Dr. B. Franklin Stahl has been appointed medical director of St. Agnes' Hospital.——Dr. W. Howard Lyle has been appointed assistant medical inspector, vice Dr. Morris H. Tindall, resigned.——Dr. Amy J. Rule, Philadelphia, has been appointed assistant physician in the State Hospital for the Insane, Norristown.

City's Milk Supply.—A symposium on "The Milk Question" in Horticultural Hall No- was conducted by the Civic Club in Horticultural Hall No- vember 17. The meeting was addressed by Dr. Joseph S. Neff, director of the Department of Health of this city; Dr. George W. Goler, director of health of Rochester, N. Y., and Drs. Joseph S. Evans, S. McClintock Hamil and Lawrence F. Flick. Dr. Neff, who presided, stated that 5.000 infants died in this city yearly as the result of the milk being placed in insanitary storage rooms. Dr. Neff favored a law requiring milk dealers to be licensed and thus place them under direct and continuous supervision of the Health Bureau. Small dealers, he said, were responsible for most mischief, because of their inadequate facilities for keeping the milk sanitary.

Dr. Goler gave a description of the combat in Rochester for uncontaminated milk. His lecture was illustrated with stereopticon views, showing the general insanitary housing and caring for cattle. He said that the death rate in Rochester had decreased since the fight for clean barn-yards, well-kept stables and sanitary dairies was instituted. He advocated laws that would give a state wide regulation over the preparation of milk for the market. Dr. Evans laid stress on inspection at the source of supply and of the rigid inspection of the facilities possessed by the city dealers. Dr. Hamill spoke on "Milk as a Food for Children," and Dr. Flick discussed "Milk as an Economical Food" and the part it plays in the treatment of tuberculosis patients.

GENERAL NEWS AND COMMENT.

Northwestern Medical Association.—A call has been issued to the physicians of the northwest to meet in Seattle in July next to organize an association comprising all the North Pacific Coast to include Washington, Oregon, Idaho and British Columbia. The meeting is to continue four days, and the arrangements are to be left in the hands of the committee from the State Medical Association of Washington.

Health of the Navy.—The annual report, made by the surgeon general, U. S. Navy, chief of the bureau of medicine and surgery, for the fiscal year 1908, to the Secretary of the Navy, shows a gratfying improvement in the general health as compared with last year, the respective morbidity per 1,000 being 691.40 and 787.23. The shortage of medical officers is still a source of embarrassment and occasions the overburdening of individual officers at certain stations to such an extent as to jeopardize efficiency. The surgeon general notes the services rendered by the newly appointed acting assistant surgeons. The advantage of this grade has been so pronounced that a probationary service in this capacity is being seriously considered as a requirement for candidacy in the medical corps. The navy medical school also represents a most potent influence for good. The need for a larger and more effective hospital corps and the raising of professional requirements in the case of hospital stewards are emphasized. The substantial improvement in the health of the naval forces afloat is evidence that hygienic principles and sanitary dictates are being more carefully observed. The ten principal causes of disability noted for the year were venereal diseases, injuries, tonsilitis, epidemic catarrh, malaria, bronchitis, rheumatism, gastrointestinal diseases, the exanthemata, and other infectious diseases. The surgeon general notes with regret the failure of congress to enact measures authorizing the employment of skilled dentists for service in the Navy. The report from one ship alone for 1907 includes 1,454 operations for almost every conceivable period of dental disorder. The dental corps bill contemplates thirty dental surgeons, fifteen of whom would probably be employed at sea and fifteen at various shore stations. The enactment of authority for the establishment of a corps of female nurses is a source of gratification to the Navy. It is believed this provision greatly enhances the possibility of increased efficiency in the medical department.

CANADA.

Corner-Stone of New Consumption Sanatorium Laid.—On November 11, the Lieutenant-Governor of British Columbia laid the corner-stone of a new sanatorium for incipient cases of tuberculosis at Tranquille.

Ontario Health Statistics for October.—There were 500 cases of typhoid fever in Ontario in the month of October, with 126 deaths, as compared with 50 deaths for the same month of 1907. There were 50 cases of smallpox. There are fifteen centers for the latter. The total number of deaths from all causes was 2,328, a death rate of 13.8 in the thousand.

Patent Medicine Laws.—It has been decided by the Dominion government that the patent medicine act of last parliament will come into force April 1, 1909. After that date any preparation which contains any drug or drugs dangerous to the public will have to be approved by experts of the department of inland revenue or bear a printed statement on the outside of each package that there is a deadly drug in the preparation, or else give the name of the drug.

Ontario Medical Council.—The Ontario Medical Council met in Toronto in special session during the week ended November 21. The discipline committee made a report on the case of two practitioners, but no action was taken thereon. The Council approved of interprovincial registration with all the colleges in the various provinces having a standard of education equivalent to that of the Ontario Medical Council. The Council did not favor reciprocity with Great Britain. The education committee recommended that the matriculation standard be raised 25 per cent.

Hospital News.—Kincardine, Ont., is to have a new hospital at a cost of $25,000.——During the past four years the citizens of Vancouver, B. C., have placed at the disposal of their general hospital board of management $400,000. This has so stimulated Victoria that it will place the matter for the extension of the Royal Jubilee Hospital of that city before the citizens by by-law shortly. This hospital treated 172 patients in October.——The Western Hospital, Toronto, has recently received a donation of $25,000 from a citizen of Toronto.——The ratepayers of Toronto will vote on the proposed grant of $200,000, divided equally between the General, St. Michael's, Grace, and the Western hospitals, at the coming municipal elections January 1.——The St. Catharines (Ont.) Hospital treated 516 patients in its last fiscal year. A new building is to be erected shortly, for which there is already in hand nearly $10,000.

Tuberculosis Exhibition in Montreal.—The formal opening of the exhibition of the Montreal Tuberculosis League took place November 18, Earl Grey, the Governor-General, presiding. The exhibition is the joint work of the English and French-speaking physicians of the city. Each year there are in Montreal 1,000 deaths from tuberculosis; in the province of Quebec about 3,000; in Canada, about 13,000. The annual loss to the Dominion is thus estimated at $39,000,000. Dr. J. George Adami, chairman of the Exhibition Committee and Dr. E. P. Lachapelle, chairman of the Executive Committee of the Montreal League invited the Governor-General to open the exhibition. The exhibition is largely due to the industry of Dr. D. Fraser Gurd; and the exhibits principally come from the board of health of Quebec, from the health department of Ontario, from the health departments of New York, Rhode Island, and Massachusetts, from the Irish Tuberculosis Association, and from the Dental Association of Quebec.

Personal.—Dr. L. C. Prevost, Ottawa, is accompanying Sir Wilfred Laurier, Canada's Prime Minister, on a trip to the Southern States.——Dr. C. D. Parfitt, for six years physician in charge of the Muskoka Free Hospital for Consumptives, Gravenhurst, Ont., and for the last seven months resident consultant to that institution and the Muskoka Cottage Sanatorium, has resigned.——Dr. Gordon has severed his connection with the Muskoka Cottage Sanatorium.——Dr. Albert H. Calfield, Toronto, has been appointed pathologist to the Muskoka Cottage Sanatorium.——Dr. W. S. Lemon, Toronto, has been added to the resident staff of the institution.——Dr. George D. Porter, Toronto, has been appointed provincial secretary of the Canadian Association for the Prevention of Tuberculosis.——Dr. Ernest Jones, Toronto, has been appointed pathologist and neurologist to the Provincial Hospital for the Insane, vice Dr. J. G. Fitzgerald, who has resigned to accept a position in Boston, Mass.——Dr. W. T. Wilson, assistant superintendent of the Toronto Provincial Hospital for the Insane, has been made superintendent of a similar institution at Cobourg.——Dr. Edward J. Stubbs, Stratford, has started on a trip around the world, stopping en route at Rochester, Minn.——Dr. Francis G. E. Pearson, medical health officer of Brantford, is seriously ill with septicemia due to an operation wound.——Dr. C. K. Clarke has been appointed dean of the medical faculty of the Toronto University, vice Dr. Richard A. Reeve, resigned.

LONDON LETTER.

(From Our Regular Correspondent.)

LONDON, Nov. 21, 1908.

Sir Jonathan Hutchinson.

Among the birthday honors conferred by the King is a knighthood for Mr. Jonathan Hutchinson in recognition of his distinguished services to medical science. The honor came as a surprise to the profession, for it was well known that the reason Mr. Hutchinson had not received any of the titles that have been conferred on lesser men was that he would not accept them. Forty years ago he refused the title that has now been conferred on him. As he is of Quaker origin his refusal no doubt was due to the distaste of that sect for such distinctions: possibly, also, his philosophical mind is above such things. He has now, however, owing to the wishes of his family, accepted a knighthood. The medical journals state that the conferring of this honor on him will be viewed by the profession with satisfaction: but the general feeling is rather one of surprise at the inadequacy of the distinction. To any one acquainted with Mr. Hutchinson's work nothing less than a peerage can seem an adequate recognition. One of the few great clinicians of all time, he ranks with Sydenham, Graves, Trousseau and Charcot, and in versatility he has surpassed even these. No other writer has made contributions of the first importance not only to general medicine and surgery, but such highly specialized subjects as dermatology and ophthalmology. Professor Osler has well described him as the only great generalized specialist which the profession has produced. With the minute knowledge of the specialist he has combined a broad and philosophic view of every subject, and has, in addition, made the various branches of medical science throw light on one another in a manner that has never been equaled.

Plague in Liverpool.

The fatal case of plague in Liverpool reported in the letter of November 7, has been followed by two others. The first victim was a man who worked on a coal barge. Now a man and his wife who occupied his cabin for the purpose of waiting on him have been attacked. Ever since the first case was found to be plague they have been kept under close observation. They were conveyed to the port sanitary hospital, where the man died, but his wife is recovering. The medical authorities have not yet determined how the disease originated. The barge was used for coaling vessels, chiefly coasters, in dock. It is supposed that the infection must have been brought from some other port. The names of the vessels coaled by the barge and the places from which they came have been communicated to the health authorities of the places. Close inspection of the barge has dispelled the idea that the disease was spread by a plague-carrying rat. Every precaution, including isolation of the patients and watching of all known contacts, has been taken. A large number of rats have been killed in the docks and examined in the municipal laboratory, but plague has not been found in any of them up to the present date.

Exemplary Damages from a "Face Specialist."

Catharine Lavin, a "face specialist," known to the public as Madame August, issues advertisements in which she professes to "rejuvenate the face," to remove smallpox marks, freckles, liver-spots, birth-marks, etc., by a "marvelous treatment." Attracted by the advertisement a woman went to her with three small-pox scars on the face. These Lavin treated with some preparation which turned the scars black and afterwards with plasters which caused the spots to coalesce into a spreading ulcer. An action for damages was brought against Lavin and she was mulcted in damages to the extent of $2,500.

Declining Marriagės and Large Decrease in the Infantile Mortality.

The quarterly returns issued by the Registrar-General show that during the three months ending September 30, 295,052 births and 146,239 deaths were registered in the United Kingdom, the natural increase of population, therefore, being 148,813. The births registered in England and Wales were in the proportion of 26.6 per 1,000 of the population, which was 1.6 below the mean rate of the preceding ten third quarters of the year. The deaths during the same period were in the proportion of 12.8 per 1,000, or 2.7 below the mean rate of the preceding ten third quarters. The deaths of infants under 1 year were in the proportion of 126 per 1,000 births as compared with an average of 175 in the ten preceding third quarters. The marriage rate for the quarter ending June 30 was only 16.7 per 1,000 as compared with an average of 17.1 recorded in the second quarters of the preceding ten years.

First Report of the Sleeping-Sickness Bureau.

The formation of a sleeping-sickness bureau in London for the collection and distribution of information on sleeping sickness was announced in a previous letter (The Journal, June 6, p. 1914). The bureau has issued the first number of its bulletin, which gives ample evidence that it will prove a valuable publication. The present number is entitled "The Chemotherapy of Trypanosomiasis," and it summarizes the various attempts to cure the disease in man and animals. The editor of the paper, Mr. A. G. Bagshawe, concludes that the employment of any one trypanocide by itself has ceased to be justifiable and that an alternation of such agents should be used. After one drug has been used for some time the trypanosomes become immune to it, but they can then be killed by the administration of some other drug. Certain experiments are described. An animal was infected with trypanosomes and treated with a trypanocide. The trypanosomes disappeared only to reappear in a few days. The same drug was again administered and the trypanosomes eliminated, but they reappeared sooner than before. The treatment was continued until the drug ceased to affect the trypanosomes and the animal died. When these trypanosomes were transferred to another animal of the same species the same drug was found from the first to be powerless. This principle was found capable of further extension. When the trypanosomes had been thus fortified in a mouse against the action of a drug, they were transferred through as many as twenty generations in rats and in every case it was found that the parasites had lost their immunity to that drug, but when they were re-transferred from the last of the series of rats to a mouse, the resistance to the drug at once became manifest. It seemed, therefore, that the individual animal played a part in the elimination of the parasites.

Tuberculous Milk in London.

During the past three months, of 92 samples of milk examined by the health department of the London County Council. 22—23.9 per cent.—proved to be tuberculous. Ten of the cows supplying the milk were found to be tuberculous and the owner undertook not to send any more milk to London from these cows, but the report does not state that he would not send it elsewhere—a procedure not impossible in the present chaotic state of the law!

Prevention of Malaria in Mauritius.

Prof. Ronald Ross was requested by the government to visit Mauritius and report on the prevention of malaria, which is very prevalent in that island. He has issued an important and interesting report on the subject, in which he recommends the following: 1. A periodical spleen census should be taken of the children. 2. In schools and on estates children with enlarged spleens should be treated with quinin. 3. Occasional house protection should be carried out. 4. Mosquito reduction where advisable should be attempted. The experience of Port Said, Klang, Port Sweetenham and Panama encourage the belief that the disease will be brought under control in this island.

Impure Soda Water.

In investigating a case of diphtheria, Dr. Collingridge, health officer of the City of London, found reason to suspect some soda water which had been purchased in a city shop. Bacteriologic examination revealed an enormous number of microbes containing cocci, sporing bacilli and large numbers of a small Gram-positive non-motile bacilli which in shape resembled diphtheroid microbes. There was no evidence that these were diphtheria bacilli, though they evidently belonged to that large class of "diphtheroid bacilli." These results showed that carbonic acid, even when under pressure, exercised little, if any, destructive action on the bacilli. A general inquiry into the purity of soda water was then made by Dr. Klein, the bacteriologist. He found that out of 36 samples, 27.7 per cent. were pure; 19.4 per cent. were fairly pure, and 52.7 per cent. were impure. Inspection of the factories showed that the source of the contamination was found usually in defects in the system of bottle washing and exposure of the water to risk of contamination in wooden tanks and absence or imperfection of coverings for the receptacles containing water. The manufacturers have now undertaken to carry out recommendations made by the health officer for securing purity of soda water. Regulations have been issued under which mineral water manufacturers must (1) obtain a certificate from the health officer of the district to the effect that their premises are in satisfactory condition; (2) they must have a bacteriologic analysis made of the water supply or when a public supply is used, a certificate of the authorities supplying the water; and (3) they must also have a bacteriologic analysis made of the finished goods. Other regulations include, in addition to those just mentioned, efficiency of filters, cleanliness of rings and stoppers, proper material for storage (wood is considered quite unsuitable), methods of bottling, washing, etc.

Critical Position of the Polyclinic.

The Medical Graduates College and Polyclinic is in a critical position. After a useful career of about ten years, it is found the membership has dropped from about 800 to 500. This is not a result of any falling off in efficiency of the institution, but is really due to the college's success, which has aroused in London an interest in postgraduate instruction. The hospitals generally have taken up postgraduate work, and no fewer than three of them—the West London, the Sea-men's Hospital, Greenwich and the North Eastern (Prince of Wales') Hospital are devoted entirely to it. These rival institutions have had the inevitable effect of withdrawing support from the Polyclinic, over which they have the great advantage of being hospitals. The Polyclinic has no beds; the patients shown there, though exemplifying some of the rarest forms of disease, consist entirely of those who are not too ill to be sent for consultation. The sum derived from the annual subscription ($5), with the fees from the tutorial classes, has never been sufficient to pay the expenses. The deficiency has been made good by voluntary increased subscriptions from a limited number of the members. Unless some new scheme can be devised there is great danger of this useful and unique institution coming to an end.

PARIS LETTER.

(From Our Regular Correspondent.)

PARIS, Nov. 19, 1908.

Conservative Treatment of Pelvic Affections.

One of our most celebrated surgeons, Dr. Richelot, has just made a communication to the Academy of Medicine on the abuse of surgery in gynecology, especially in the cases of "nervous arthritic patients," uninfected, without notable lesions, but affected with uterine congestion, dysmenorrhea, uterine catarrh, hemorrhages, etc. With such patients, hot water, employed in the form of vaginal injections and general and perigastric douches, gives excellent results, provided it is employed according to a rigorous system. It is not sufficient to make injections of two liters (two quarts) of water at 45 C.; it is necessary to insist on abundance of water, a high temperature, and regularity of injections. To obtain the best results the vaginal injection should consist of 80 to 100 liters (21 to 26 gallons) of water. This is the vaginal douche as given at the springs of Luxeuil. The general douche ought not to be reserved exclusively to neurologists; the gynecologists may also make advantageous use of it in localized affections of the true pelvis. For this purpose hot-water therapy requires, to be sure, special apparatus, but the difficulty in using—which is, after all, common to all physical agents—is no reason for underrating its value. The method has two principal indications: in uterine congestions, it renews the existence of those nervous arthritic patients whose pains, hemorrhages and dysmenorrhea have withstood everything; in pelvic infections, in which operation appears to be obligatory, but in which there are strong reasons for not operating, such as the youth of the woman or her desire to have children, hot-water therapy is capable of bringing about unexpected complete resolutions. And, even if the relief of pelvic congestion does not cause the disappearance of pains or the complete resolution of tumefactions of the adnexa and of pelvic exudates, it is still useful in diagnosis, to determine the true indications, proper procedure and to limit surgical intervention.

The French Red Cross.

The French Red Cross is made up of three societies for assistance to wounded soldiers, the Association of French Ladies, the Union of the Women of France, and the Society for Aid to Wounded Soldiers. The latter, which is the oldest of the three, having been founded in 1865, has now 55,000 members. It is now building a hospital-school where its members may perfect their practical education as nurses. The principal pavilion, which is the only building as yet completed, was turned over to the president of the society, Marquis de Vogüé, on November 14, by Professor Guyon, president of the medical commission and of the instruction of the Red Cross. Up to the present the ladies of the Red Cross have attended only the dispensary-schools, which taught them to make dressings but left them ignorant of the care to be given to wounded men in hospitals. The construction of the hospital cost 550.000 francs ($110,000) and was paid for by gifts and public subscriptions without drawing on the war fund of the society, which amounts to 6.000,000 francs ($1.200.000). Apart from the relief distributed to the wounded in the Crimean, Italian and Franco-Prussian wars and the colonial expeditions, the society has sent 1,233,447 francs ($246,689) in relief to foreign red cross societies, for the Russo-Turkish, Spanish-American, South African and Russo-Japanese wars.

In case of war, the society would be able to furnish nearly 3,000 nurses and 26 auxiliary field hospitals attached to the various corps of the army, each one containing 100 beds. In case of mobilization it could, moreover, put at the disposal of the Minister of War 538 auxiliary territorial hospitals, with a total of 20,602 beds. It also has 88 railway station infirmaries, in the most important stations of our various railway centers, the purpose of which is not merely to give medical and surgical care to the sick and wounded passing through the station, but to give temporary nourishment and care to those who are unable to continue their journey.

Election of Dr. Quénu to the Academy of Medicine.

Dr. Quénu, professor of operative medicine at the Paris Medical School and surgeon of the Cochin Hospital, has been elected titular member of the Academy of Medicine, in the section of surgical pathology, to fill the place of Professor Terrier, who died last April.

Museum of Hygiene.

Since 1890, there has existed in Paris a little museum of hygiene, containing among other things, the exhibits which figured in the Paris pavilion of hygiene at the exposition of 1900, and which have to do especially with the sanitation of dwellings, the emptying of latrines and sewers, etc. There is now a plan to complete and to install the collections so as to make of them a real model museum of hygiene and sanitation. It will comprise the twelve following sections: Air and light (composition, meteorology; lighting of the city; lighting, heating and ventilation of the house); water (composition and bacteriology; flowing waters of rivers and springs, ozonation; distribution, filters, private baths, etc.); food and clothing (composition of foods, nutritive value, adulteration, sterilization of milk; hygiene of clothing, impermeability, etc.); preventive hygiene (disinfection, measures against fire, materials of construction); hygiene of infancy (feeding of infants, gymnastics); establishments such as hospitals, asylums, soup-kitchens; hygiene of special establishments (arrangement, heating, etc., of barracks, prisons, schools, cheap houses); residues of life (cemeteries and cremation; household refuse; rain-water and slops, night soil; sewers; emptying of used waters); public conveyances (omnibuses and fiacres; neatness, ventilation, disinfection, cleaning, etc.); smoke; demography; library.

Declaration of Contagious Diseases.

Dr. Widal's recent report to the Academy of Medicine on epidemics, took up, among other questions, that of compulsory declaration of contagious diseases. The law of 1902 requires this declaration of the attendant physician; but the great majority of physicians consider the requirement inconsistent with the superior obligation of professional secrecy. This law being about to undergo revision, the Academy of Medicine has been invited to give advice in regard to modifications. Widal contends that the physician's obligation should be limited to making the diagnosis, leaving to the head of the family or to the landlord, if the patient has no family near him, the duty of making the declaration to the authorities. The Academy, however, finally adopted the proposition to make the physician and the head of the family jointly responsible for the declaration. Practitioners regret this decision, which practically restores the physician's complete responsibility, since he will be subject to prosecution if the head of the family neglects his duty, which will doubtless happen frequently.

Criminality and Alcoholism.

For several years, criminality has increased in truly disquieting proportions. The principal cause appears to be alcoholism. Below is an instructive table showing that, since the law on free traffic in liquors, the increase in the number of murders, suicides and cases of insanity has been almost parallel to the increase in the consumption of alcohol.

	1881.	1905.
Number of licenses..................	367.829	473.593
Hectoliters of alcohol manufactured...	1,822,000	2,609.000
Murders brought to justice............	182	274

BERLIN LETTER.

(From Our Regular Correspondent.)

BERLIN, Nov. 14, 1908.

The Temperance Movement.

A few weeks ago the German League Against the Misuse of Spirituous Beverages celebrated its silver jubilee. The conditions now are undoubtedly more favorable than when the society was founded. The combined efforts of physicians, national economists, public officials, etc., have resulted in a marked reduction in the consumption of alcohol in recent years. One can only rejoice at this fact. It is true that a large part of the national wealth is still wasted in the consumption of intoxicating beverages every year, wealth that might have been put to better uses. While we do not take the stand of the total abstainers, that every drop of alcohol is a drop of poison and that, therefore, all use of liquor on account of its admittedly great dangers, should be most energetically opposed, yet, on the other hand, it can not be denied that, even in medicine, the importance of alcohol as a stimulant and nutrient has been considerably overrated. Until the beginning of the campaign against the abuse of alcohol the consumption of beer and wine was almost a measure of the national feeling (*Massstab für die nationale Gesinnung*), especially in academic circles. To-day this is happily changed. One need no longer feel ashamed of a moderate use of alcohol or even of total abstinence either in private circles or in the inns. Still there remains much to be done in this direction. As the renowned hygienist of Munich, Professor Gruber, showed in a recent address on the alcohol question, beer is still drunk very extensively. In 1905, 129 liters (33 gallons) per capita were used by the German people, and even if the use of brandy has diminished the consumption of absolute alcohol amounts to 9.6 liters (4½ gallons) per capita per year. Even now 3,000,000,000 marks ($720,000,000) are spent for alcoholic beverages in Germany yearly, and many workmen's families spend from one-fifth to one-fourth of their earnings for such drinks. In Munich, which is, indeed, the greatest beer city of the world, immense amounts of beer are still consumed. However, even here, gratifying progress is not to be denied, for in 1907 the consumption of beer was less by 200 liters per head than it was twenty years ago.

It is evident that the authorities are supporting the campaign against intemperance as far as possible. The organs of the social workmen's insurance societies, the railroad managers and the municipal officials are taking part in this campaign by issuing appropriate regulations, establishing places for the sale of alcohol-free drinks, and by disciplinary punishment of drunkenness and the discharge of intoxicated employés. Some railroad managers have lately installed in the workshops automatic vending machines for bouillon capsules, which are gladly used by the workmen to prepare for themselves, with the aid of hot water, a palatable broth.

For a long time apparatus for furnishing Seltzer water and for making coffee have been placed in the workshops. The use of milk, tea, coffee and nutritious broth is constantly increasing among the railroad employés. The traffic in these articles is either in the hands of the company or in those of the workmen's societies, which apply the profits to benevolent purposes.

It is to be hoped that the cause will make further progress. At any rate, we have already reached more advanced ground than our neighbor, Russia. According to a statement of the *Petersburg medizinische Wochenschrift*, there are sold from the three depots in St. Petersburg alone—in Russia the sale of brandy is a state monopoly—about 3,928,000 kegs (*Eimer*) of brandy; 445 official brandy shops attend to the retail trade in addition to about 2,900 private establishments of various sorts. As is easy to understand, the consumption of the poorer sorts of brandy is markedly greater than that of the better. Denatured spirits are very often drunk either after chemical treatment or even unaltered. Under Russian conditions it is not strange that the officials in Warsaw recently forbade the delivery of a course of lectures organized by a temperance society on the injurious effects of alcoholism. A reduction in the amount of liquor consumed would check the flow of the fountain now yielding an income for the government and for the venal officials.

Progress of the Public Health in Germany.

It is not strange, in consideration of the persistent efforts in all the various departments of hygiene, that the public health in our country has made remarkable progress. This is evident in the reduction in the number of deaths in proportion to the population. This reduction is especially noticeable in the large cities, where in the last thirty years a reduction of the mortality of from 25 to 30 per cent. has been recorded. To be sure, this diminished mortality does not affect the period of infancy, a fact to which we called attention in a previous letter. According to statistics recently issued by the imperial statistical bureau, the expectancy of life for all ages has materially increased in the last decades. A child of 10 years has to-day the prospect of living 5 years longer than he had thirty years ago; a man 20 years old, about three years; a woman of 20, about three and a half years. Even in the case of a man of 70, the average expectation of life is now about five months and that of a woman of 70 about six months longer than formerly.

Pharmacology

LLOYD'S CONSUMPTION CURE.

The Latest Developments in the Exploitation of J. Q. Lloyd's Many Named "Specific."

In The Journal, November 21, we described J. Q. Lloyd's "scheme to work the doctor" by means of his "consumption cure," Aicsol or Anti-Phthisis (Lloyd) or Lloyd's Specific, as it has been called. His latest scheme, it will be remembered, was to put the "cure" on the market under still another name and sell it "direct to consumptives" "on the mail-order plan." We learn that its new "mail-order" direct-to-the-public name is Re-Stor-All—a cognomen which gives it one more claim to classify with "patent medicines" of the Pe-ru-na type and other hyphenated nostrums.

ALSO A CURE FOR PARALYSIS.

From one of the testimonials that Lloyd is going to send "direct to the public," we learn that Re-Stor-All, *alias* Aicsol, *alias* Anti-Phthisis, *alias* Lloyd's Specific, not only cures tuberculosis, but also paralysis. In this interesting and instructive testimonial, dated October 27, a St. Louis lawyer states that he took the first bottle of Re-Stor-All "on the 26th day of July." (According to Mr. Lloyd, Re-Stor-All will not be on the market before December 1!) After curing himself of tuberculosis this lawyer thought that this preparation might be good for some other conditions—and in this conjecture, it seems from his report, he was not disappointed:

> "I advised my mother, who is 70 years of age, and who was afflicted with paralysis of one side of her face and her right arm for 20 years, to try Re-Stor-All. Her face, which had been drawn to one side and one eye-lid which had been dropped down, and also her right arm, was *completely cured by the use of one bottle*." —[Italics ours.—Ed.]

We shall be surprised if Mr. Lloyd, with his highly developed business instinct, does not advertise this multi-christened preparation under still another name as a cure for paralysis. The remedy unquestionably possesses great potentialities, if not of a remedial, at least of a financial nature.

LLOYD'S HEADQUARTERS.

The following letter from a St. Louis physician who paid a visit to the "headquarters" of this concern is enlightening:

St. Louis, Nov. 21, 1908.

To the Editor:—I called this morning at the place of the Judd Q. Lloyd Chemical Co. at 548 DeBaliviere Avenue. After telling Mr. Lloyd that I was interested in his medicine and that I had heard a great deal about it, he gave me a sample bottle of Aicsol. He told me that the "formula" was correct, and that each ingredient was in the proportions as stated on the bottle. He said that the secret of the medicine was in the way of combining the different ingredients and as that was his discovery he would not disclose it.

As he thought that I had some money, he then tried to sell me some stock and gave me an "inside" to his scheme. He said that the articles for incorporation were now at the state capital and that they were going to reorganize a new company and call it the Re-Stor-All Chemical Co., and that they were going to put up Re-Stor-All, which is to be sold to the laity.

On questioning him, he said that it was the same thing as Aicsol, which was intended for physicians' use. He said that the way they were going to reach the public was through the daily press, and that they were going to advertise in the daily newspapers of all the large cities, a half-sheet every day, and the laity reading these will send for treatment.

He said that they were going to charge $5.00 a month, payable in advance, and in passing he said our profit would be $4.50. I suggested that all the people that sent for medicine would not have consumption, and he replied that any persons that had had a brother or friend die of consumption, if they only had a pain in their stomachs, would think that they, too, had consumption and would send for a bottle of his medicine.

After the new company was in operation they intended, Mr. Lloyd said, to start a tent colony for tuberculosis a short distance from his so-called laboratory. In connection with this he said that a certain high federal officeholder of the city of St. Louis was interested in the company, and that he had some land that he wanted to sell the company.

As a further inducement, he told me that if I took stock in the company he would give me a position in his office, as he needed a physician in the office to answer letters from the people, to prescribe doses and the like, and also to visit his tent colony. He said that he was not registered in this state and for that reason he needed a registered physician. He showed me a letter he got from a patient with five dollars enclosed for one month's treatment.

On request, he showed me through his "laboratory," a room about thirty by forty feet, which was about one-fourth filled with copies of the *St. Louis Star* of Nov. 7. He showed me a brick affair about six by ten feet square which looked like an oven, and this he told me contained a copper retort in which he mixed his medicine. There was a gas range in this room also, on which were two kettles. There were a couple of barrels which, he said, contained the finished article, and there were a good many packages put up. In the same room were twenty-four or twenty-five girls wrapping up this edition of *The Star* and sending out circulars to physicians about taking stock.

In the yard was an old tent in which he said a consumptive lived, but who was shining shoes the day I called. In a yard were eight rabbits and one guinea-pig. He said there were more of the pigs under the ground. He showed me a dog, "Kate," which he said he had cured of consumption four times: there was also another dog there. In a small shed were three monkeys, one, which was a little thin, he said had consumption. He also had a chicken coop with several chickens in it. He said that he mixed chicken's blood with tubercle bacilli and injected this to produce tuberculosis in the animals. In the yard were also six or eight barrels that appeared to be empty, and I think he said that tar came in them.

In his office were twelve stenographers, all very busy writing letters of some kind. He said that he was sending out one hundred thousand marked copies of the *St. Louis Star*, and it looked fully that much. He also said that he was not doing any work with animals now nor was he experimenting, as he had done all that, and now he was busy putting up the medicine. ——— ————, M.D.

PURCHASING THE PRESS.

In his letters to physicians, referring to the "article" which appeared in the *St. Louis Star*, Lloyd emphasizes the fact that "this write-up is given us *gratis*." Evidently this is the "free enlargement" scheme adapted to the exigencies of journalism. Who has not been approached by the suave gentleman who offers to enlarge your photograph *gratis*—providing you are willing to pay a nominal sum to cover the cost of "our handsome gilt frame and the expense of packing?" What enterprising newspaper, unhampered by an inelastic journalistic conscience, is there but would be willing to furnish a write-up "gratis"—providing the beneficiary thereof was willing to contract for 100,000 copies of the issue which contained it? Such methods of subsidizing the press may seem more crude than those adopted by the Proprietary Association of America, but possibly they are just as effective.

THE CURE NOT A CURE.

It is, of course, unnecessary to deny that this or any other of the hundreds of "consumption cures" on the market will cure the disease, or is of any value. The fact is, practically all of these "cures" are founded on heartless cupidity and downright fraud; occasionally some ignorant enthusiast honestly believes he has something of value, but these self-deluded exploiters are rare; as a rule, the promoters are downright swindlers.

In the earlier stages of his operations, Lloyd was sufficiently unsophisticated in the *finesse* of "patent medicine" exploitation to publish the names and addresses of physicians who had written favorably concerning his preparation. A riper experience in the nostrum business has taught him that such testimonials prove to be boomerangs: hence we now find all physicians' names excluded, because, as Lloyd artlessly says, "medical ethics do not permit the use of physicians' names." We investigated some of those earlier cases in which it was possible to make inquiries and to get at the facts. In every instance, as might be expected, not only was the "cure" a failure, but the physicians who had made the first reports had lost their enthusiasm.

Said one:

> "I can not see that the J. Q. Lloyd remedy for tuberculosis gave me any results that were satisfactory. I do not care to try them longer."

And another:

> "Anyone who allowed himself to be drawn into a 'skin game' such as this evidently is, should not have the confidence of other practitioners. . . . . I can simply state through my desire to better my t. b. cases I have been made the assistant of a fake."

And a third:

> ". . . . the two patients spoken of did do well for a while on the Lloyd treatment, but it was only temporary, both going the way of all such cases, to the grave."

And these expressions of opinion, it should be remembered, are from men who, in the early enthusiasm of trying a new "remedy" had written praising Lloyd's specific.

WHAT IT ALL MEANS.

The promoters of such "cures" know full well how eagerly the hapless consumptive grasps at any therapeutic straw—useless or fraudulent; they also know that there is an inbred belief on the part of the laity that "medicine" will "cure" consumption; they know, too, that the panic fear of the consumptives' relatives will make them believe that every "pain in their stomach" is consumption, and that they, too, "will send for a bottle." But knowing all this, such promoters are willing to make capital out of the fear, the ignorance and the pitiable conditions of those afflicted with tuberculosis. They are in the business, frankly and baldly, for the dollars and cents; but what shall be said of physicians who lend the weight of their names and the authority of their profession that they, too, may soil their hands with the tainted money of the nostrum-exploiter?

And this is the disgraceful thing—for us—in this disreputable business: that some physicians are partners in it. It seems hardly believable, but we have sufficient evidence to warrant the conclusion that at least some physicians have been so misled as to invest in the stock of this concern. Have the glowing advertisements of certain proprietary houses which offer for sale their "stocks" and "bonds" to physicians so hypnotized the medical profession that some of its members are willing to become financially interested in the exploitation of that cruellest of fakes—a consumption cure?

In the words of Samuel Hopkins Adams: "Every man who trades in this market, whether he pockets the profits of the maker, the purveyor or the advertiser, takes toll of blood. He may not deceive himself here, for here the 'patent medicine' business is nakedest, most cold-blooded. Relentless greed sets the trap and death is partner in the enterprise."

More British Nostrums Investigated.

In continuing its articles on "Certain Secret Remedies," the *British Medical Journal*, Oct. 17, 1908, p. 1193, takes up preparations for rupture, considering Rice's treatment for rupture and the "Healine" treatment. As these are not sold to any extent in this country information regarding them is of minor importance to us, but they illustrate the usual methods of nostrum-makers. Rice's treatment pretends to furnish a "developing lymphol" which will enable Nature to repair the breach in the wall. According to the advertisements, the "developing lymphol—Nature's true assistant"—is said to be "a vitalizing and restorative application that is absorbed into the tissues through the skin pores, just as rain-drops sink into the ground to soften the earth and keep it fertile." The company furnishes a mechanical appliance to restrain the outbreaking intestines while the "lymphol" is working. The appliance is supplied with the "lymphol" at prices varying from $5 to $21.50, according to grade. The "lymphol" alone costs $4 for a four-ounce bottle, the cost of which is estimated at 18 cents. According to the *British Medical Journal*, analysis showed the "lymphol" to consist of capsicum resin and essential oils of origanum, peppermint and spearmint, dissolved in alcohol. The results of the analysis of Healine were mainly negative.

Correspondence

The Specificity of Complement Fixation.

Chicago, Nov. 22, 1908.

To the Editor:—Your editorial on the above subject (November 21) has unfortunately not rendered quite clear the present status of this question. The validity of the principle of complement fixation itself (discovered by Bordet) has been amply confirmed by numerous observers. This has furnished a means of identifying various substances with which an organism may be invaded and against which it reacts. The scope of its applicability extends beyond the detection of bacteria and their products to other substances, as proteids, lipoids, etc. It is specific in every sense to a particular antigen (and probably to a particular group of antigens) and the serum containing the corresponding antibodies.

It has become a matter of history that the complement fixation in the serum reaction for syphilis, as was evident in the early works of Fleischmann and myself, does not arise from the interaction of the specific cause of syphilis and its corresponding antibodies, but that it occurs from the fact that there are certain substances present in the blood of syphilitics, not contained in non-syphilitics, which will unite with the extracts of luetic and normal organs, and with certain lipoids, as lecithin, the sodium bile and salts, etc., and in so doing anchor complement.

It was early demonstrated by Landsteiner that the blood of animals inoculated with *Trypanosoma equiperdum*, in the presence of organ extract and complement, caused fixation of the latter. He suggested that it might be found that the blood of patients suffering from infections produced by trypanosomes, spirochetes, etc., might likewise cause a deviation of complement, but this could in no wise lessen the practical value of the serum reaction for syphilis, as these parasites represented infections which could not be confused with syphilis; on the contrary, that this really broadened the scope of the reaction, as suggested by Wassermann, to other infections which would not come into consideration from a differential standpoint with syphilis.

Reports concerning the result of the reaction during a brief period following the eruptive stage of scarlet fever, in view of the above experiences, have suggested the possibility of scarlet fever being caused by a spirochete, thus supporting the view of a group-specificity of the reaction. There have been considerable differences of opinion as to the result of the reaction in scarlet fever. These are attributed, as I can confirm, to differences in the antigens employed. The inhibition of hemolysis in these cases is slight and simply emphasizes the necessity for caution under other circumstances in interpreting slight inhibitions of hemolysis.

The experiments of Wolff-Eisner and Ascher in regard to complement fixation in tuberculosis, which had previously been thoroughly threshed out by Wassermann and by Morgenroth and their pupils, can hardly be looked on as having any bearing on the syphilis question. These are made with a view to determining whether it was possible to demonstrate the presence of antituberculin in the serum of patients with tuberculosis, who had not been treated by tuberculin. This they thought they were able to show, but it is probable that the quantities of antigen (tuberculin) used (0.5 c.c.) were often sufficient of themselves to produce an anticomplement action, something which happens with organ extracts when they are employed in too large quantities or too great concentration.

The comment that the blood of syphilitic patients, pneumonia patients, etc., gave the complement-fixation reaction with tuberculin, but that the blood of normal individuals always reacted negatively, suggests a point on which we are not all equally clear. A positive reaction in immuno-diagnostics indicates a constitutional reaction against a definite antigen. A positive reaction may be expected as long as an active immunity obtains, irrespective of what other diseases exist. Hence patients with syphilis might give a tuberculin reaction, because they are or had at some time been infected with tuberculosis; and similarly patients with tuberculosis might give a syphilis reaction.

The value of the serum reaction for syphilis, instead of being lessened by the enormous amount of experimental work done in connection with it, has been constantly reaffirmed. It has become an established immuno-diagnostic test for syphilis in Europe. The attacks this reaction has withstood in the past two years on the Continent will probably be repeated here, but it is to be hoped, as in the former instance, that they will be founded on actual experiences with it.

William J. Butler.

[Comment.—It would seem that the writer of the above letter has himself conceded the main question at issue, namely, the lack of specificity, from the standpoint of disease, of the complement-fixation reaction with certain antigens. As to whether or not such lack of specificity impairs the diagnostic value of the Wassermann syphilis reaction, the editorial referred to was intentionally somewhat non-committal. The statement cited by Dr. Butler, however, that the other diseases in which a positive reaction is obtained are such as could not be confused with syphilis, is scarcely accurate, particularly in the case of yaws.

In regard to the work of Wolff-Eisner and Ascher, it is improbable that their antigen alone sufficed to prevent hemolysis, inasmuch as no inhibition was obtained when the antigen was used in the presence of normal serum. The authors themselves state that "the tuberculin employed prevented hemolysis slightly only in quantities from 0.5 c.c. up. This effect can, therefore, be neglected with the dilutions used." Dr. Butler's suggestion that the positive reaction obtained by them in cases of various non-tuberculous diseases might be due to a previous or coexisting tuberculous infection, is of course a possibility. It surely would be a remarkable coincidence, however, were all their pathologic subjects to have a tuberculous history, and their normal subjects to be free from that infection!

Finally, the alleged unfortunate failure of the editorial to render quite clear the present status of the question is perhaps unavoidable in view of the lack of clarity of the present status of the question itself.—Ed.]

Psychotherapy.

Chicago, Nov. 20, 1908.

To the Editor:—The letter by Dr. Jacobson in The Journal, Nov. 14, should receive the serious attention of the profession. The endeavor to establish a higher grade medical curriculum, as well as the efforts to encourage a better class of young men to take up the study of medicine, no doubt will bear fruit ere long. The cheap medical college will then die a natural death and believers in physical culture, Fletcherism and similar cults will learn the real truths about right living. The problems facing the profession to-day, however, are of different nature, the pseudoscientist cults—church clinics, Dowieites, new thought, eternal progress, spiritualistic healers, etc.—are the real obstacles that confront the profession and those that must be dealt with intelligently ere long.

In my opinion there is but one way to solve these problems, and that is by encouraging the scientific study of the principles underlying all this class of phenomena. Psychology is now receiving the attention it deserves. Psychic phenomena, which constitute the real underlying basis of all the above named cults, are still largely tabooed by the scientist in America. In Europe, however, many eminent physicians and practically every scientist is interested in this subject. The facts in relation to them are no longer doubted and it is to be hoped that ere long some scientist will make known some of the laws that control these manifestations. All knowledge is gained by observation, and though the problems presented seem insurmountable the rule laid down by the late Lord Kelvin in 1871 holds good now as it has during the past thirty-five years; he then said: "Science is under bonds, by the eternal principle of honor, to look fearlessly in the face of every problem that is presented to her."

I am firmly convinced that the scientific investigation of psychologic problems ultimately will be of great benefit to humanity and a practical help to the honest seeker after truth. The time is ripe for the intelligent, thoughtful man of science to encourage the study of this phenomenon with the same care and consideration that has characterized his research into the fields of biology, pathology, bacteriology and chemistry.

The amount of literature on these subjects in practically all the popular magazines is paving the way for a greater field for the charlatan than he had ever dared to hope for.

Daniel S. Hager, M.D.

Tacoma, Wash., Nov. 26, 1908.

To the Editor:—Dr. Jacobson's letter, in The Journal November 14, appeals to me as very rational. It must be conceded that the very fact of the existence of so many well-patronized irregular methods of treatment reflects on the adequacy of results at the hands of physicians. From staid old Boston to happy-go-lucky Tacoma or Seattle the irregulars are profusely supplied with material for the laying on of hands and the exercise of faith. They have existed too long and have done too much service to be longer derided; the half-truth of their dogmas must be acknowledged.

Of all the efforts, genuine or counterfeit, to fill the gap the recent movement in Boston with the Rev. Dr. Worcester at its head probably is recognized by those acquainted with its intricacies as the nearest to the ideal yet devised. With the diagnostician's verdict in his hands, the Emmanuel worker does what the regular practitioner does not do in the class of nervous cases selected: he makes use of that wonderful and vital force of most men, the religious part of them, for the relief of the physical. We physicians mentally appeal to a patient and demand his confidence; the Emmanuel worker communes with the *spiritual man and demands his faith*. In psychotherapy the tie between the healer and the one who would be healed can not be made too strong and the aid can not be made too powerful.

Looking at the matter squarely, can we wonder that coadjutors whom we do not recognize have sprung up from the wrong sources to supplement our insufficiency? I think we are awaking with a start to our weaknesses. How much more potent would a movement such as that which originated in Boston be had it sprung from the bosom of the learned medical profession! How much more sensible and practical would it be for the physician to call in the spiritual adviser than for the spiritual adviser to be compelled to call in the physician—in his own domain!

It is not possible for us perhaps to be "all things to all men." Some of us consult a pathologist to make use of his technic; we send our prescriptions to the druggist to be compounded; we have a masseur on our list for the cases needing massage; why not have for the mutual benefit of all concerned a trained religious worker on our staffs to utilize the spiritual in conjunction with our established treatment. I agree with all those who truly believe that the spiritual natures of our neurasthenic and mental patients are agents too powerful to be longer disregarded.

Edward A. Rich, M.D.

A Pioneer in the Fight Against Quackery.

St. Louis, Nov. 23, 1908.

To the Editor:—The department of Medical Education and State Boards of Registration in The Journal is one of the highest interest and importance, and, in looking over the contents I have more than once thought that the prime mover in the great undertaking for better things which this department evidences did not receive during life that full recognition at the hands of the medical profession which his achievements deserved. Nor has this acknowledgment been publicly made since his death.

I refer to the late Dr. John H. Rauch, secretary for many years of the State Board of Health of Illinois, who, in all matters pertaining to medical education in America, was a pathfinder, pioneer, waymaker—one who fought the good fight for honesty and thoroughness in medical teaching and training with such persevering firmness that the fruits are now being gathered throughout almost the entire length and breadth of this continent, and whose well-earned fame can in no wise be dimmed through the luster gained by those who may come later.

As secretary of the State Board of Health of Missouri for a period concurrent with a part of the public life of Dr. Rauch I was in sympathetic official touch and agreeable personal relations with him, and can testify to the friendly aid often extended to clear up the new and difficult questions that arose with respect to the standing of schools, dealing with advertising frauds, examination and licensing of medical applicants, and the like.

Where the body of Dr. Rauch was buried is not known to me, nor whether the spot is marked by any memorial adequately showing the vastness and value of his work to the public and the profession; but, in view of his life and labors, the question may be asked whether it is not a serious obligation resting on the organized profession of Illinois to take the lead in a movement to raise in some appropriate place a memorial in marble or bronze that shall signify to later generations his rightful place in the great struggle in which he was the chief leader, *censor medendi, pontifex medicus.*

The evidences of his worth and work should appeal to every reputable medical college now extant in the land, for in testimony of his merit may be shown the graveyards where a host of fraudulent concerns were buried through his energy, pluck and ability. Therefore such medical schools, and the various state sanitary and licensing boards should welcome the opportunity to aid in forwarding a movement to render a fit tribute to the memory of a man whose services were fundamental, beneficent, and of enduring value to the welfare of his fellowmen.

George Homan, M.D.

Hyperemic Treatment Not New.

Sidney, Ohio, Nov. 21, 1908.

To the Editor:—The advertisement of a volume entitled "Bier's Hyperemic Treatment" calls to my mind the fact that this alleged new discovery is new neither in principle nor in application. It is not, as the advertisement alleges, a therapeutic discovery of greater importance than any within recent years. In principle it is simply an amplification of the cupping-glass and adapted to a wider range of utility. I have in my possession the old air-pumps and several of the parts of an apparatus which was adapted to apply this method to every part of the human body, including the whole trunk except the head. The outfit was well made of japanned tin, glass, and pure rubber or rubber cloth, and would fit over any of the prominences of the body, as the knee, shoulder and hip. The receptacles for the body, arm and leg were made of tin. Even the fingers were provided for. By whom this apparatus was made or devised is not known, but it was supposed to be patented and was sold for several hundred dollars. It was owned by a man who had a mania for "patent rights," and at his request I made trials of its merits at intervals as opportunity offered. The results were not more satisfactory than the results of other methods of treatment.

It is well said that it is not a panacea. Like other therapeutic measures, in selected cases it has a field of usefulness. But to herald it as a new discovery of great importance is nonsense. Of course the treatment can be applied to every variety of lesion and disease, but the results usually will be disappointing. Verily there is nothing new under the sun—especially in hyperemic treatment. It was in use half a century ago.

D. R. Silver.

Instruction in Medical Ethics.

Memphis, Tenn., Nov. 27, 1908.

To the Editor:—Dr. Bryant's letter concerning the teaching of medical ethics, which appears in The Journal, November 28, is more than timely. It should be a part of the curriculum of every medical school to instil these principles into the minds of their students through a series of lectures on medical ethics, for during their student days the future practitioners are in the most receptive mood for such instruction. In the school with which I am connected a course of lectures in medical ethics has been conducted for two sessions, and every graduate of the institution when he is handed his diploma receives at the same time a copy of the "Principles of Medical Ethics of the American Medical Association."

Richmond McKinney.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

CUGUILLERE'S SERUM.

Philadelphia, Nov. 7, 1908.

To the Editor:—In The Journal, Nov. 7, 1908, page 1626, Dr. Eugene Caravia advocates the use of Cuguillère's serum, which he says "consists of allylum sulphid 1 gram, tincture of myrrh 1 gram, and Hayem's glycerinated serum 100 grams. It is a yellow liquid, with a strong odor of garlic and is non-toxic." Please tell *me if this is a proprietary* remedy or a proper therapeutic measure *to be employed by reputable physicians; also* where it can be obtained, if it is as capable of beneficial influences as is indicated in the brief abstract referred to. Inquirer.

Answer.—*The formula given* above is the one announced by Dr. *Cuguillère in a short communication* on his "serum" before the surgical section of the International Congress on Tuberculosis at Paris (1905; see *Transactions,* ii, 11). It appears, therefore, to be no serum at all, because the "serum" component is merely Hayem's fluid or artificial serum, the formula of which is usually given as mercuric chlorid 0.5, sodium sulphate 5, sodium chlorid 1, distilled water 200, with an addition of glycerin. The two other components are the "active" ones, according to Dr. Cuguillère, who has a strong belief in the "extraordinary power of garlic and the ethereal oils containing organic sulphur." Allylum sulphid $(C_3H_5)S$ is the principal component of the ethereal oil of *Allium sativum,* and like the latter (garlic) has had some reputation as a remedy for tuberculosis. Regions in which much garlic is consumed, such as *Galicia,* are reported comparatively free from tuberculosis; and R. Koch has also experimentally demonstrated that the bacillus is little resistant against the various aromatic substances, especially the oil of garlic and the allied oil of mustard. From a report of Caravia ("Cuguillère's Serum in the Treatment of Tuberculosis," *Medical Record,* N. Y., 1908, lxxiv, 520) we learn however, that Cuguillère, who prepares and distributes his "serum" himself, holds that since the synthetic allylum sulphid is inactive, it is necessary to employ the "organic" sulphur from fresh juices of brassica, allium, watercress, horseradish, etc. Therefore the formula given can not indicate the true composition of this "serum." It is given by intramuscular injection at doses from below 5 c.c. to the "useful maximum dose of 15 c.c." There are so few reports of the use of this preparation that it is impossible to arrive at any definite conclusion regarding its value.

CALOMELOL OINTMENT.

St. Louis, Nov. 16, 1908.

To the Editor:—I am in receipt of an advertising pamphlet entitled "Calomelol Ointment (Heyden)." Among other things I find therein an article "by Professor Neisser and Dr. Siebert," from which I quote (page 6): "*Calomelol ointment contains 45 per cent.* of Calomelol, which *consists of calomel in a* colloidal or soluble *form.* Calomelol . . . is soluble in water one part to fifty, and also in blood serum, in the secretions of the body, etc. It contains 66 per cent. of metallic mercury. In addition Calomelol ointment contains 2 per cent. of free metallic mercury." Until now I supposed that calomel (of which Calomelol "consists") was insoluble in any "form" in water, and contained very nearly 85 per cent. of mercury. *Please explain the matter to me.*

Joseph Grindon.

Answer.—The ordinary insoluble calomel is *formed* when a solution of sodium chlorid is treated with mercurous *nitrate.* According to the patent specification, a water-soluble *colloidal* calomel is made by treating a solution of sodium chlorid *in the* presence of a proteid with mercurous nitrate; the product is precipitated by alcohol, collected and dissolved in water *with the* aid of a little alkali. This is the product sold as Calomelol. The exact constitution of this product has probably not been *established,* but it is generally believed to be calomel which, *through the intervention* of proteid in its formation, has not become insoluble. A number of similar colloidal products have been prepared. *Of these* the best known are the colloidal forms of metallic *gold and* metallic silver, the latter having been introduced in medicine. The colloidal silver and colloidal gold are supposed to be metallic silver and gold, differing from the metallic form in being water-soluble.

HYPODERMIC USE OF MERCURY IN SYPHILIS.

Nebraska City, Neb., Nov. 14, 1908.

To the Editor:—What is the best salt of mercury for hypodermic use in syphilis? In a formula containing *benzoate of mercury,* sodium chlorid and water, is not a *chlorid of mercury* formed?

F. S. Marnell.

Answer.—This subject has been discussed in The Journal by W. S. Gottheil ("Ten Years' Experience in the Treatment of Syphilis by the Intramuscular *Injection of Insoluble* Mercurials," Aug. 3, 1907, xlix, 365); by R. Wernigk ("*Twelve Years'* Experience in the Treatment *of Syphilis by Intravenous* Injections of Mercury, Arsenic and Iodid of Sodium," *Feb. 22, 1908,* l, 609); and by H. G. Klotz ("Mercurial Treatment for Late Manifestations of Syphilis," this issue, under *Original Articles*); *also in this* department ("Value and Technic of *Mercurial Injections,"* Sept. 5, 1908, li, 859). Various salts are recommended, chiefly the chlorid, salicylate, benzoate, succinimid, *and* the *iodo-phenol-sulphonate* (sozoiodolate). The benzoate is *soluble in water with difficulty,* but is much more soluble in the *presence of sodium chlorid.* The salts exist in solution *chiefly in the form of ions, so that it is* perhaps not correct to say that the chlorid is formed. On concentration the benzoate, *as it is the less soluble, would* separate from the solution first, but it is not *practicable to determine the* exact form in which these compounds exist *in solution. The sozoiodolate* also is insoluble; it is dissolved by *the aid of sodium iodid* (mercury sozoiodolate 1 *gm.,* sodium iodid 3 *gm., water to make* 100 c.c.); and in the solution the mercury *probably exists in combination* with iodid.

ARSENIOUS ACID TREATMENT OF EPITHELIAL CANCER.

Scottsbluff, Neb., Nov. 17, 1908.

To the Editor—On page 1740 of The Journal, November 14, I note reference to a formula of Cerny and Trunecek, of Prague, which I infer was given in The Journal at one time.

May I ask where I can obtain this formula?

A. G. Emerson.

Answer—Several other correspondents ask the same question, hence *we reply at some length. The original illustrated article by* S. Cerny and C. Trunecek, of Prague, was published in the *Semaine Medicale*, Paris, *March 12, 1899,* page 100. They warn that the *method is indicated only* when the glands show no signs of *induration,* but the more ulcerated the surface, they add, the more rapid *the action* of the arsenic, as also when the cancer cells are young. *As the adult cells* on the surface are thrown off in the eschar and *younger cells* are reached, *the healing process proceeds more rapidly.* The eschar drops off without hemorrhage and the raw surface that is left is treated as an ordinary wound. The characteristic eschar which forms can not be produced by the arsenic on an ordinary wound. *It seems to result from the* special combination of the arsenious acid with the albumin of the cancer cells. The *method was referred to in* The Journal, May 7, 1898, *and* April 8, 1899. From the last mentioned issue we quote:

"The treatment of epithelial cancer with daily applications of a mixture of arsenious acid, 1 gram; ethyl alcohol and distilled water, each 75 grams, reducing later to 50 and 40 (vide Journal, XXX, p. 1116), first dehydrates the cancer-cells by the action of the alcohol. The protoplasm of the cells is then coagulated by the arsenic. The cells of the cancerous connective tissue degenerate and a serous exudation is induced, which in turn affects the cancer-cells already mummified by the arsenic. A demarcation inflammation then ensues on the sound parts, followed by the elimination of the neoplasm as a foreign body, without hemorrhage. The forms amenable to this treatment are those without indurated ganglia in which local treatment is possible. Its chief advantage over surgery is that it destroys every cancer-cell without injuring the sound tissue. An analgesic can be added to the solution if the applications are very painful; morphin may be necessary for the severe *pain that occasionally follows,* an hour later, especially in case of *carcinoma. The writers urge the general adoption* of this harmless, *effective cure.* Three weeks are sufficient in the early stages. Extensive lesions *may require a few months.*"

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending November 28, 1908:

Torney, George H., col., relieved *from* present duties in San Francisco, Dec. 1, 1908, and directed to repair to Washington, D. C., for duty in the office of the Surgeon General.

Kennedy, J. M., maj., directed to report for assignment as commanding officer, Army General *Hospital,* San Francisco, Dec. 1, 1908.

Pierson, R. H., capt., granted leave of absence for ten days.

Barney, F. M., M.R.C., ordered from temporary duty at Ft. McHenry, Md., to Ft. Howard, Md., for temporary duty.

Griffis, F. C., M.R.C., ordered to *accompany* troops from Ft. Sheridan, Ill., to Ft. D. A. Russell, Wyoming, and return to station.

Wren, R. J., M.R.C., sick leave of absence extended one month.

LeHardy, J. C., M.R.C., order for sailing for Philippine service amended; will sail Jan. 5, 1909, instead of Dec. 5, 1908.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending November 28, 1908:

Passed Assistant Surgeon P. T. Dessez, ordered to temporary duty at the Naval Hospital, Mare Island, Cal.

Assistant Surgeon G. D. Hale, detached from the *New Hampshire* and ordered to the *Idaho*.

Assistant Surgeon F. P. W. Hough, detached from the Naval Hospital, Portsmouth, N. H., and ordered to the Naval Proving Ground, Indian Head, Md.

Assistant Surgeon F. P. W. Hough, detached from the Naval Proving Ground, Indian Head, Md., and ordered to the *New Hampshire*.

Surgeon O. D. Norton, detached from the Naval Recruiting Station, New York, and ordered to continue duty in attendance on officers and enlisted men of the Navy and Marine Corps in New York not otherwise provided with medical attendance.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service for the seven days ended Nov. 25, 1908:

Kalloch, P. C., surgeon, directed to proceed to Oak Grove, Me., for special temporary duty.

Carrington, Paul M., surgeon, on being relieved by Passed Assistant Surgeon H. S. Mathewson, directed to proceed to San Diego, Cal., and assume charge of the station.

Wertenbaker, C. P., surgeon, detailed to represent the service at the thirteenth annual meeting of the Seaboard Medical Association of Virginia and North Carolina, at Washington, N. C., Dec. 1-3, 1908.

Mathewson, Henry S., P. A. surgeon, on being relieved by Passed Assistant Surgeon C. W. Wille, directed to proceed to Fort Stanton, N. M., and assume command.

Grubbs, S. B., P. A. surgeon, directed to report at the bureau for further instructions.

Gwyn, M. K., P. A. surgeon, on being relieved by Assistant Surgeon William M. Bryan, directed to proceed to Baltimore, Md., and report to the medical officer in command for duty and assignment to quarters.

Holt, John M., P. A. surgeon, granted 1 day's leave of absence, Nov. 14, 1908.

Wille, C. W., P. A. surgeon, on being relieved by Passed Assistant Surgeon J. T. Burkhalter, directed to proceed to Cleveland, Ohio, and assume command.

Burkhalter, J. T., P. A. surgeon, on being relieved by Surgeon W. P. McIntosh, directed to proceed to Gulf Quarantine Station and assume command.

Collins, G. L., P. A. surgeon, granted 3 days' leave of absence from Nov. 17, 1908, under Paragraph 189, Service Regulations.

Bryan, William M., asst.surgeon, on expiration of present leave of absence, relieved from duty at the New Orleans Quarantine Station, and directed to proceed to the South Atlantic Quarantine and assume command.

Goldsborough, B. W., acting asst.-surgeon, granted 6 days' leave of absence from Nov. 28, 1908, under Paragraph 210, Service Regulations.

Gustetter, A. L., acting asst.-surgeon, leave of absence for 10 days from Nov. 15, 1906, granted Nov. 9, 1908, amended to read from Nov. 16, 1908.

Hill, Eugene W., acting asst.-surgeon, granted 4 days' leave of absence from Nov. 24, 1908, under Paragraph 210, Service Regulations.

Light, S. D. W., acting asst.-surgeon, granted 22 days' leave of absence from Nov. 17, 1908.

Minthorn, Henry J., acting asst.-surgeon, granted 7 days' leave of absence from Nov. 23, 1908, under Paragraph 210, Service Regulations.

Tappan, J. W., acting asst.-surgeon, directed to make inspections at Del Rio and Hidalgo, Texas, Nov. 17, 1908.

APPOINTMENT.

Dr. Carlisle P. Knight appointed an acting assistant surgeon for duty at Kobe, Japan, Nov. 21, 1908.

BOARD CONVENED.

Board of medical officers convened to meet at the Marine-Hospital in Baltimore, Md., Nov. 25, 1908, for the purpose of conducting physical examinations of the members of the graduating class of cadets of the Revenue-Cutter Service; Passed Assistant Surgeon W. C Billings, chairman; Assistant-Surgeon A. J. Warner, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended *Nov. 27, 1908*:

SMALLPOX—UNITED STATES.

California: Oct. 31-Nov. 7, Los Angeles, 1 case; San Francisco, 2 cases.

Indiana: Oct. 31-Nov. 7, Elkhart, 3 cases; Fort Wayne, 1 case; LaFayette, Nov. 2-16, 3 cases.

Kansas: Oct. 31-Nov. 7, Topeka, 2 cases; Wichita, 1 case.

Kentucky: Nov. 7-14, Covington, 4 cases; Lexington, 1 case.

Ohio: Cincinnati, Nov. 5-12, 5 cases.

Washington: Spokane, Oct. 31-Nov. 7, 1 case.

Wisconsin: La Crosse, Oct. 31-Nov. 16, 5 cases.

SMALLPOX—FOREIGN.

Brazil: Rio de Janeiro, Sept. 27-Oct. 18, 1,420 cases, 652 deaths; Santos, Sept. 13-Oct. 14, 36 cases, 15 deaths.

Canada: Oct. 31-Nov. 7, Halifax, 1 case; Victoria, 1 case.

Egypt: Cairo, Oct. 7-21, 4 cases, 2 deaths.

India: Bombay, Oct. 13-20, 6 deaths; Rangoon, Oct. 3-10, 1 death.

Indo-China: Cholen, Sept. 25-Oct. 3, 1 death.

Italy: General, Oct. 25-Nov. 1, 39 cases; Naples, Oct. 25-Nov. 1, 8 cases, 1 death.

Mexico: Mexico City, Sept. 19-Oct. 3, 9 deaths.

Norway: Christiania, Oct. 10-24, 6 cases, 1 death.

Russia: St. Petersburg, Oct. 10-17, 4 cases, 1 death; Warsaw, Sept. 25-Oct. 10, 9 cases.

Spain: Barcelona, Oct. 25-31, 4 deaths; Valencia, Oct. 24-31, 2 cases.

Turkey: Constantinople, Oct. 18-Nov. 3, 7 deaths.

CHOLERA.

China: Hongkong, Sept. 19-26, 1 case, 1 death.

India: Madras, Oct. 3-16, 29 cases, 19 deaths; Rangoon, Oct. 3-10, 1 death.

Indo-China: Sept. 27-Oct. 3, Cholen, 2 cases, 2 deaths; Saigon, 1 case, 1 death.

Russia: Odessa, Sept. 19-26, 4 deaths; St. Petersburg, Nov. 4-9, 258 cases, 29 deaths.

Straits Settlements: Singapore, Sept. 19-Oct. 3, 2 deaths.

PLAGUE.

Brazil: Rio de Janeiro, Sept. 29-Oct. 18, 16 cases, 7 deaths.

Chile: Iquique, Oct. 12, 4 cases.

China: Hongkong, Sept. 19-26, 1 case, 1 death.

Egypt: General, Oct. 14-Nov. 3, 20 cases, 12 deaths; Alexandria, Oct. 14-Nov. 3, 6 cases, 4 deaths.

India: General, Sept. 26-Oct. 10, 4,977 cases, 3,699 deaths; Bombay, Oct. 13-20, 16 deaths; Rangoon, Oct. 3-10, 3 deaths.

Indo-China: Sept. 26-Oct. 3, Cholen, 9 cases, 9 deaths; Saigon, 8 cases, 7 deaths.

Peru: General, Oct. 814, 27 cases, 13 deaths; Callao, 2 cases, 2 deaths; Lima, 2 cases, 1 death.

Marriages

Benjamin F. Roller, M.D., to Miss Tracy Helen Aylwin, both of Seattle, June 5.

George E. Pfahler, M.D., to Miss Frances Simpson, both of Philadelphia, November 21.

Frederic Dinkler, M.D., to Miss Rufus Cochran, both of Fort Cobb, Okla., November 10.

Norman O. Nelson, M.D., Madison, Wis., to Miss Edith Smith, of Baltimore, November 21.

Joseph Conn, M.D., New Orleans, to Miss Hortense Holzman of Shreveport, La., November 2.

George O. A. Kellogg, M.D., Nampa, Idaho, to Miss Effie Cowley, of Boise, Idaho, November 11.

W. Wade Doster, M.D., St. Johns, Kan., to Miss Helena Wilson of Philadelphia, November 11.

J. Gill Allan, M.D., to Miss Blanche Claypoole, both of Edgewood, Ill., at St. Louis, October 28.

Samuel F. Hassler, M.D., to Miss Mae Reed, both of Harrisburg, Pa., at Baltimore, September 30.

Anthony F. Dougherty, M.D., Ashley, Pa., to Miss Teresa L. Murphy, of Plains, Pa., November 10.

Job Theophilus Edwards, M.D., New Haven, Pa., to Miss Lizzie Collins, of Pittsburg, November 16.

James S. Bates, M.D., Erwin, S. D., to Miss Blanche Ethel Peirson, of Gascoyne, N. D., November 5.

Neal Edwards Sellers, M.D., Mobile, Ala., to Miss Nell Brown, of Birmingham, Ala., November 10.

Frank U. Swing, M.D., Avondale, Cincinnati, to Miss Louise Hocker, of Cincinnati, November 24.

J. Elmer Porter, M.D., Pottstown, Pa., to Miss Annella Newborn, of Royersford, Pa., November 18.

George Lee Fosque, M.D., Onancock, Va., to Miss Mary N. Fitchett, of Cape Charles, Va., November 18.

G. Edward Campbell, M.D., Hampton, Tenn., to Miss Mary Sue Hurt, at Washington, D. C., November 5.

Perley Raymond Brenton, M.D., Mineral, Wash., to Miss Ruth Ella Greathouse, of Seattle, November 12.

A. E. Goldsmith, M.D., Columbia City, Wash., to Miss Florence A. Sheppard, of Chicago, September 1.

William Sterling Robertson, M.D., to Miss Ellen Booker Roller, both of Charleston, W. Va., November 19.

Lowick Thomas Patillo, M.D., Atlanta, to Miss Leola Ottila LeRosen of Shreveport, La., November 24.

George M. Belhemeur, M.D., Negaunee, Mich., to Miss Louise C. Werner of Lake Linden, Mich., November 9.

Jacob Sieberth, M.D., Hazelhurst, Wis., to Mrs. Marion Van Dyke Ramsey, of Grand Rapids, Wis., November 18.

John C. O'Connor, M.D., Manchester, N. H., to Miss Helen Jackson Raymond, of Salem, Mass., at Marblehead, Mass., November 17.

Deaths

John C. Hupp, M.D. Jefferson Medical College, Philadelphia, 1847; in 1859 secretary of the Section on Practice of Medicine and Obstetrics of the American Medical Association, and chairman of the Committee on Necrology; for ten years treasurer of the West Virginia State Medical Association; and for a like period treasurer of the Medical Society of the City of Wheeling; for several years state vice-president of the Jefferson Medical College Alumni Association; city physician and secretary of the Wheeling board of health in 1864; physician to the Children's Home in 1873; state vaccine agent from 1863 to 1878; consulting physician to the city hospital; president of the Ohio County board of supervisors from 1863 to 1866; a member of the district board of education from 1873 to 1879; and for many years president of the local board of U. S. pension examining surgeons; died at his home in Wheeling, November 18, from senile debility, aged 88.

Frank Lemuel Adams, M.D. Cooper Medical College, San Francisco, 1883; a member of the American Medical Association; treasurer of the Pacific Association of Railway Surgeons; formerly president of the Medical Society of the State of California and the Alameda County Medical Association; one of the founders, president and professor of clinical surgery in the Oakland College of Medicine and Surgery; president of the Oakland Board of Health; surgeon to the Santa Fe system and the Oakland Traction Consolidated Company; died suddenly at the home of his cousin in Oakland, from angina pectoris, November 20, aged 50. The Oakland Chamber of Commerce, at a special meeting, held November 21, passed resolutions laudatory of Dr. Adams, expressive of the loss sustained by the city in his death, and directing that a memorial tablet be placed in the directors' room of the Chamber of Commerce.

George R. Graham, M.D. University of Maryland, Baltimore, 1883; of Baltimore; a member of the Medical and Chirurgical Faculty of Maryland; a veteran of the Civil War; a member of the board of U. S. pension examining surgeons of Baltimore since 1889; department commander of the G. A. R. in 1890; and surgeon general in 1892; past president of the Grand Army Club of Maryland; died in the Maryland General Hospital, November 19, from pneumonia, aged 64.

Casper Coiner Henkel, M.D. University of Pennsylvania, Philadelphia, 1857; a member and twice vice-president of the Medical Society of Virginia; surgeon of the Thirty-seventh Virginia Infantry and later brigade surgeon, division surgeon and corps surgeon in the Confederate service throughout the Civil War; died at his home in New Market, Va., November 16, from diabetes, aged 73.

Charles Cunningham Schley, M.D. University of Georgia, Augusta, 1857; University of Paris, France, 1860; surgeon of the Seventh Georgia Battalion and later division surgeon in the Confederate service throughout the Civil War; one of the heroes of the yellow-fever epidemic of 1876 in Savannah; died at his home in that city, November 19, from cerebral hemorrhage, aged 72.

Charles Dexter Noble, M.D. University of Louisville, 1868; a veteran of the Civil War; surgeon of the Fifth Ohio Infantry, U. S. V., in the Spanish-American War, and for two years thereafter an acting assistant surgeon in the Army; and during nearly all that time on duty in the Philippine Islands; died at his home in Oberlin, Ohio, November 16, aged 65.

Samuel Dauphin Culbertson, M.D. Jefferson Medical College, Philadelphia, 1866; a member of the American Medical Association; a veteran of the Civil War; a member of the house of delegates of the Illinois State Medical Society and the oldest practitioner of Ford County; died at his home in Piper City, November 12, from pneumonia, aged 69.

George W. Perkins, M.D. Harvard Medical School, Boston, 1886 division surgeon of the Union and Southern Pacific Railway at Ogden, Utah; and visiting surgeon to the Union Pacific Railway Hospital; one of the founders, and a member of the staff of the Ogden General Hospital; died in that institution, November 18, from intestinal paralysis, aged 58.

William J. Martin, M.D. Hahnemann Medical College, Philadelphia, 1877; a veteran of the Civil War; a member of the staff of the Pittsburg Homeopathic Hospital for twenty-five years, and president of its medical board; died suddeny at his home, November 17, from cerebral hemorrhage, aged 60.

Samuel John House, M.D. Vanderbilt University, Nashville, 1876; a member of the Tennessee State Medical Association and a member of the board of aldermen of Franklin Tenn.; died at his home November 16, a week after an accident in which he was struck by a train at Mallory Station.

Rufus Revill Applewhite, M.D. New Orleans School of Medicine, 1860; a Confederate veteran; from 1877 to 1887 a member of the Mississippi legislature from Lincoln County; and in 1899 sheriff of that county; died at his home in Brookhaven, November 21, from paralysis, aged 70.

Edward Irving Ford, M.D. College of Physicians and Surgeons, New York City, 1860; surgeon of volunteers during the Civil War; and in charge of the Army General Hospital at Nashville; died at his home in Binghamton, N. Y., November 16, from heart disease, aged 84.

Frederick Arthur Van Buren, M.D. Northwestern University Medical School, 1904; of Lead, S. D.; a member of the American Medical Association; formerly assistant surgeon to the Homestake Mining Company; is said to have been murdered recently in Colorado, aged 32.

Benjamin M. Atkinson, M.D. Jefferson Medical College, Philadelphia, 1852; a member of the Medical Society of Virginia; for many years physician to the Virginia School for the Deaf and Blind, Staunton; died at his home in that city, November 18, aged 78.

William D. Scott, M.D. Medical College of Ohio, Cincinnati, 1896; a member of the American Medical Association; for many years health officer of Georgetown, Ky.; died at the Good Samaritan Hospital, Cincinnati, November 18, from heart disease, aged 39.

Hugh Morison Ives, M.D. New York University, New York city, 1870; major and surgeon during the Civil War; died at his home in Parksville, N. Y., November 19, from paralysis, due to injuries sustained in a fall down a precipice, four years before, aged 69.

James Edward Tompkins, M.D. University of Maryland, Baltimore, 1891; of Fredericksburg, Va.; a member of the American Medical Association; died in Johns Hopkins Hospital, Baltimore, November 18, a few hours after a surgical operation, aged 41.

Benjamin A. Ver Nooy, M.D. Bellevue Hospital Medical College, New York City, 1896; of Pulteney, N. Y.; died in a hotel in Penn Yan, N. Y., November 18, from the effects of a gunshot wound, said to have been self-inflicted while despondent, aged 35.

Orin S. Mills, M.D. Medical College of Ohio, Cincinnati, 1888; house physician to the Columbus (Ohio) State Hospital for the Insane; died in Gallipolis, Ohio, November 24, from a gunshot wound of the head, said to have been self-inflicted, aged 48.

Joseph Alston James, M.D. Medical College of the State of South Carolina, Charleston, 1852; chief surgeon of Kershaw's division, in the Confederate service, during the Civil War; died at his home in Columbia, S. C., November 23, aged 79.

Robert Edward Smith, M.D. Medical College of Alabama, Mobile, 1882; a member of the Medical Association of the State of Alabama; died suddenly at his home in Greenville, November 16, from heart disease.

William L. Fleming, M.D. New York Homeopathic Medical College, 1873; of New York City; a veteran of the Civil War; died in Lincoln Hospital, New York City, November 20, from meningitis, aged 73.

Englebert Frenz, M.D. University of Giessen, Germany; of Saginaw, Mich.; for several terms a member of the board of education; died in St. Mary's Hospital, Saginaw, November 7, from diabetes, aged 68.

Francis Patrick Lewis Cantlie, M.D. McGill University, Montreal, 1902; died at the home of his parents in Montreal, November 10, from the results of a spinal injury received several years before, aged 29.

George W. Norris, M.D. University of Maryland, Baltimore, 1872; while suffering from nephritis, and temporarily insane, shot and killed himself at his home in Baltimore, November 20, aged 62.

Armand Mignault, M.D. University of Victoria College, Cobourg, Ont., 1886; a member of the Massachusetts Medical Society; died at his home in Salem, November 13, from cancer, aged 64.

John H. Purefoy, M.D. Jefferson Medical College, Philadelphia, 1859; for several years postmaster of Furman, Ala.; died at his home in that place, November 22, from cerebral hemorrhage, aged 72.

Boyle Ludwell Ellett, M.D. Missouri Medical College, St. Louis, 1861; a Confederate veteran; postmaster of St. Clair, Mo., for eleven years; died at his home in St. Clair, October 31, aged 69.

Joseph Shreve, M.D. Philadelphia University of Medicine and Surgery, 1866; Hahnemann Medical College, Philadelphia; died at his home in Burlington, N. J., November 19, aged 86.

George W. Todd, M.D. University of Tennessee, Nashville, 1900; health officer of Rutherford County, Tenn.; died from fever at his home in Rucker, November 20, aged 31.

Leona Lebus, M.D. Johns Hopkins Medical School, Baltimore, 1900; of Los Angeles, Cal.; died in a hospital in San Francisco, after a surgical operation, November 20.

David W. McClure, M.D. Medical College of Ohio, Cincinnati, 1885; of Cincinnati; died, November 1, from skull fracture due to a fall in an epileptic seizure, aged 49.

John Newton Poage, M.D. Medical College of Ohio, Cinnati, 1848; died at his home in College Hill, Cincinnati, October 29, from valvular heart disease, aged 83.

William A. Ratliff, M.D. Tulane University, New Orleans, 1886; of Edwards, Miss.; died at the infirmary, Vicksburg, Miss., November 16, from nephritis, aged 45.

John C. Connell, M.D. University of Nashville, 1880; formerly of Goodlettsville, Tenn.; died at his home in Nashville, November 22, from heart disease, aged 52.

Walter Marsh Jackson, M.D. Harvard Medical School, Boston, 1868; of Stamford, Conn.; died suddenly from heart disease in that city November 15, aged 66.

John S. Van Marter, M.D. Philadelphia College of Medicine and Surgery, 1886; died at his home in New Brunswick, N. J., November 20, aged 71.

Lewis S. Blackwell, M.D. University of Pennsylvania, Philadelphia, 1857; died at his home in Perth Amboy, N. J., November 18, aged 75.

Christian William Davis, M.D. Jefferson Medical College, Philadelphia, 1890; died at his home in Philadelphia, November 14, aged 45.

Joseph Sills Campbell, M.D. Queen's University, Kingston, Ontario, 1890; died at his home in Rochester, N. Y., November 6, aged 38.

George W. Horn, M.D. Bennett Medical College, Chicago, 1873; died at his home in Sharon, Wis., November 20, aged 70.

Society Proceedings

COMING MEETINGS.

SOUTHERN MEDICAL ASSOCIATION.

Second Annual Meeting, held at Atlanta, Ga., Nov. 10-12, 1908.

(Continued from page 1893.)

Diagnosis and Pathology of Malaria.

Dr. William Krauss, Memphis, Tenn.: The majority of physicians rarely resort to blood examination in diagnosis of malaria. The symptoms and the quinin test are not to be omitted entirely, but they are often very unreliable. Even though there exist no doubt as to the case being one of malarial fever, and even though the physicians can tell from the symptoms with which clinical type and which stage of the cycle he is dealing, the examination of the blood enables him to predict events concerning which he would be absolutely in the dark without it. A numerical idea can be obtained of the infection, developing secondary groups, multiple species, resting bodies, latent infection, and effects on the blood can be detected, sometimes, indeed, it is possible to recognize the presence of another disease. It is important to recognize species, and since each of the three can give quotidian, tertian, remittent, continued and pernicious fever, latent infection and cachexia, no other method is open except examination of the blood. The differential leucocyte count is of diagnostic importance, and I am in the habit of showing it by three columns of 100 units each, the first representing the lymphocytes, the second the large mononuclears, and the third the polymorphonuclears.

Treatment of Malaria.

Dr. J. A. Witherspoon, Nashville, Tenn.: The treatment of malaria is divided into hygienic and medicinal. The room should be light, well ventilated and thoroughly screened. The patient should be in bed, and have a daily warm bath. The diet should be nutritious, the bowels should be kept regular, and large amounts of water should be taken. Quinin is the specific, and it may be given by mouth, by rectum, hypodermically, or intravenously. Internally the sulphate is best, hypodermically the hydrochlorid. In the intermittent forms 15 or 20 grains should be given from four to six hours before the chill is expected. The patients should be kept on small doses of quinin for at least two months, and on the seventh, fourteenth and twenty-first days the initial dose should be repeated. In the estivoautumnal variety calomel should be given in broken doses preceding the quinin, which is preferably given in acid solution. From 15 to 30 grains of quinin should be given in this way, in divided doses, during the twenty-four hours. Treatment should be continued from six to ten weeks after the attack. If anemia is marked, iron and arsenic should be given. In the pernicious types quinin should be given hypodermically or intravenously, from 10 to 15 grains of the hydrochlorid or the bisulphate every three hours until a dram is in the system at least four hours before the time for the chill to return. In malarial cachexia arsenic and quinin should be administered over a prolonged period. I am convinced that in all cases of this type a change of residence is necessary. When quinin could not be used I have obtained the best results with the tincture of eucalyptus. In certain cases splenectomy has been fairly successful.

Discussion on Malaria.

Dr. H. M. Folkes, Biloxi, Miss.: In my work I find practically only two methods of satisfactory administration of quinin—intravenously and in solution by mouth. In hospital work I give it altogether by the latter method.

Dr. D. Harvey Dillon, New Orleans: The dose of quinin in pernicious malaria is the amount required to produce its full physiologic action, and it is important that we should be able to tell when we have cinchonized the patient. In this form of malaria it is best administered hypodermically.

Dr. D. L. Wilkinson, Montevallo, Ala.: In the estivo autumnal type for some years I have used a combination of quinin, gelsemin, elixir of vitriol and capsicum, which seems to be almost specific when borne by the stomach. In the treatment of enlarged spleens and indurated livers in the chronic forms I have had very happy results by the use of the iodid of potassium and the muriate of ammonia.

Dr. C. S. Bel, New Orleans: I recall a female patient who died of pernicious malarial fever, and the plasmodium, besides being found in the blood, pericardium, meninges, and spleen, was also present in a seven months' fetus.

Dr. J. H. White, New Orleans: I think that not enough stress has been laid on the isolation of the individual patient. Some years ago I had charge of a hospital, thinking it was properly screened, but I found that one of my chronic patients who had not been out of the ward for a year contracted an estivoautumnal attack of malaria in the ward.

Dr. William Litterer, Nashville, Tenn.: I have found Dr. Krauss's method of showing the leucocyte count of distinct aid, although not uniformly correct. There are certain conditions in which the transition is so close that it is impossible to tell from the leucocyte count whether we are dealing with malaria or some other condition.

Dr. Victor G. Heiser, U. S. Public Health and Marine-Hospital Service: Does Dr. Witherspoon know of any patient with malarial fever, microscopically diagnosed, that recovered without any treatment whatsoever?

Dr. W. Krauss: In using quinin hypodermically, the solution should be dilute, a large syringe should be used, and the needle should be plunged in as far as possible.

Dr. J. A. Witherspoon: I am glad Dr. White mentioned the screening of the patient, because that is something which is sadly neglected in private practice. I have had patients go to the mountains and remain without treatment and recover. I do not agree with Dr. Thayer as to the hypodermic method. I have seen cinchonism produced by it repeatedly. The solution used should be very dilute, and the injection should be made in the lumbar region or the buttocks, with a large syringe. The intravenous method is all right theoretically, but very few physicians will use it in practice. Screen the patient, kill the mosquito wherever you can, and see that the quinin is properly absorbed; that is often overlooked. Give it a little too long rather than too short a time.

Anorexia.

Dr. George M. Niles, Atlanta: The cases I wish to deal with are those more pronounced cases of anorexia which are so perplexing in their management. It is not always easy to remove the cause. Lack of appetite associated with the wasting or suppurating diseases should be combated energetically. Nourishment should be administered often and in concentrated form. When anorexia is accompanied by foul taste and bad breath, a test meal should be ordered, and lavage used if indicated. When some mental condition is the cause it is important to employ every means of suggestion at our command. In some cases of anorexia rectal feeding may have to be employed to bridge over a crisis. Much aid may be obtained from drugs judiciously administered, as hydrochloric acid, pepsin, nux vomica, or the bitter stomachics. I believe that when we can consider the stomach as only one part of the alimentary tract, but reflexly in sympathy with every other organ in the body; when we can realize that, while stomach troubles affect the disposition, moody tempers also produce marked functional disorders of the stomach, and when we can add to medicinal and hygienic measures a well-considered force of psychic influence, we shall be able to control and cure 95 per cent. of these patients.

Serum Diagnosis of Syphilis.

Dr. William Litterer, Nashville, Tenn.: I examined 72 patients in whom syphilis could be reasonably excluded. All gave negative reaction, In 3 patients with tabes 1 was positive and 2 negative. In 6 latent cases the patients contracted syphilis from 10 to 15 years ago, and received the classical treatment. Two of these gave a positive reaction, the others were negative. The patient with primary syphilis (chancre showing *Spirochæta pallida*) gave positive reactions. Vigorous antisyphilitic treatment was at once instituted. In one week after treatment those with positive reactions gave no apparent evidence of attenuation. One month later the reactions in these 2 patients had nearly disappeared. Four patients with chancroid and 2 with gonorrhea gave negative reactions. In 7 patients examined before the appearance of secondary symptoms (in 3 the spirochete was found) 6 were positive and 1 doubtful. This reaction of Wassermann is specific. It is found in more than 85 per cent. of all patients with syphilitic manifestations. Diagnosis can be cleared up in those unfortunate individuals who go through years of their lives never knowing whether they have or have not contracted this dread disease. By such a method of diagnosis the great sociologic questions concerning the marriage of syphilitic patients, the detection of syphilis in wet nurses, etc., is of incalculable value. Lastly, it is of inestimable merit in the differential diagnosis in every department of medicine.

DISCUSSION.

Dr. William J. Butler, Chicago: An enormous number of presumably non-syphilitic patients suffering from various infections, and also others apparently healthy, have been examined with a view to determining whether this reaction would be found under any other circumstances than where the patient had syphilis, and almost uniformly they have proved negative. The few instances in which they have proved positive would well come under these probable luetic cases among the great number of non-syphilitic cases. This would seem to prove for clinical and practical purposes the specificity of the test. In manifest syphilis, that is, patients with skin manifestations, lesions of the mucous membranes, etc., positive results will be obtained from 95 to 98 per cent. of cases. It is remarkable how early this test will appear in syphilis. I have had ten patients examined before the appearance of secondaries, and in all the reaction was positive. This will be of some value to syphilographers when they are uncertain as to whether what appears as a soft chancre is accompanied by a hard chancre. In two such cases the test proved positive, and the patients subsequently developed secondary manifestations. In internal medicine, neurology, pediatrics, surgery, etc., I believe that this test becomes an exceedingly valuable aid to us. In the so-called latent cases of syphilis about 50 to 60 per cent. will give a positive reaction. It is presumed that this 50 per cent.of positive reactions would coincide well with the 50 per cent. of patients with syphilis which would show old visceral lesions of syphilis at postmortem. It is assumed on this basis that the test, when positive in every case, indicates activity of the syphilis, whether invading some internal structure or affecting the nervous system. As to parasyphilitics: in paresis from 90 to 100 per cent. will give a positive reaction. Such a high proportion, however, is not found in tabes, about 60 per cent. being positive. Patients under treatment with mercury and the iodids sufficiently long will not give a positive reaction, and it is assumed, from this and from the fact that the vast majority of patients with symptoms give the test that a positive reaction is a definite indication for treatment, irrespective of what the examination of the patient shows. Something can be told as to prognosis, but no clinician will rely absolutely on this or any other test in regulating his treatment, and will naturally resort to periodic treatment without the reaction, but the reaction is an invaluable aid in the control of treatment.

Dr. William Krauss, Memphis, Tenn.: If it were not for the extreme importance of a disease like syphilis so complicated a test would fall of its own weight, and probably it will do so anyway. All of these specific reactions against infections are more of an evidence that the individual is making a fight against the infection than they are evidence of the disease itself.

Dr. W. Litterer, in closing: In all probability this test will not be employed except in large medical centers, although I do not consider it so difficult as estimating the opsonic index. I believe that the reaction will be simplified. Dr. Varney, of Detroit, has used a modification of Klausmann's method by taking 1 c.c. of blood serum from a suspected patient and mixing with that a few drops of a 1 per cent. solution of taurin. This is set aside and a precipitate indicates a positive reaction. He has experimented with 205 cases, and found it positive in 94 or 95 per cent. He has never obtained a positive reaction from a patient who was not suffering from syphilis.

Practical Results in Philippines in Reducing Mortality by Elimination of Intestinal Parasites, Especially the Hookworm.

Dr. Victor H. Heiser, Public Health and Marine-Hospital Service: In Bilibid prison over 3,000 prisoners are constantly confined. From 1902 to 1905 there was an uninterrupted increase in the death rate until a mortality of over 200 per thousand per annum was reached. The sanitation of the prison was then transferred from the control of laymen to the Bureau of Health. Work which had for its object the relief of this condition was begun at once, overcrowding was relieved, sewage disposal improved, adjacent lowlands filled in, the sick placed under treatment more promptly, and other well-recognized measures were put into effect. The death rate in a few months' time fell to about 75 per thousand per annum, but further reduction seemed impossible. For a period of about six months every effort was made to lower it, but without succeess. A study of the hospital patients showed that they were dying with ailments to which they should not have succumbed. Their powers of resistance were evidently impaired. The habits of the natives of the Philippines suggested a remedy. The evidence pointed to some extraordinary drain on the system. There was plenty of food, but evidently imperfect nourishment. With a view to discovering the cause, a routine practice of microscopically examining the feces of every prisoner was inaugurated; 84 per cent. were found infected with intestinal parasites. Of these, 60 per cent., or 52 per cent. of the total number of prisoners, had hookworms, 59 per cent. had whipworms, 23 per cent. had amebas, and 21 per cent. harbored some other species of parasite. Over half of the prisoners were hosts for at least two kinds of worms. Active therapeutic measures were taken to rid the prisoners of the causes of these debilitating troubles, and the death rate fell to less than 20 per thousand. Some thousands of stool examinations made in the Philippines outside of Bilibid show that about the same percentage of infections may be expected among the general population. It is believed that the foregoing facts warrant the assertion that in countries where hookworm disease is prevalent its eradication will produce better results in diminishing the mortality than any one other public health measure which has yet been advocated.

DISCUSSION.

Dr. Martin Crook, Columbus, Ga.: In my work as county physician for the past three years I have come in contact with this disease more than any other in the class of people which it affects. It strikes me that when we have a disease that affects sometimes every member of a family, making them unable to work, except possibly one or two days a week, there is no method of computing its economic importance in the Southern States. I have not found it yet in the colored race, although I do not mean by that that they are entirely immune.

Dr. W. F. Westmoreland, Atlanta, Ga.: My experience with surgical cases has been that with some degree of frequency uncinariasis is a prominent factor in contributing to the surgical conditions. I am sure that in an appreciable percentage of cases the recognition of this fact and the examination of the feces will lead to a clearing up of symptoms which were unjustifiably attributed to the surgical condition or to an operation, and put these patients on the road to early convalescence.

Dr. William Litterer, Nashville, Tenn.: Several cases of uncinariasis have been reported from Nashville, and I have seen two cases in people who had never left Davidson county. In these cases the condition was first recognized by finding a marked eosinophilia.

Dr. William Krauss, Memphis, Tenn.: The physician who expects to make a diagnosis from eosinophilia is apt to go wrong. In malaria the spleen may or may not be enlarged, and in uncinariasis it is always contracted. But the only sure diagnostic point is a microscopic examination of the stools.

Dr. V. C. Heiser: I hope the Southern Medical Association will give all the influence which it undoubtedly has in the South to assist Dr. C. W. Stiles, of Washington, D. C., in the hookworm campaign which he is about to undertake.

Influence of Education on the Development of Women.

Dr. D. L. Wilkinson, Montevallo, Ala.: For eleven years I have been studying the educational problem from the standpoint of its immediate and remote effects on the development of women. During these years I have been physician for more than 4,400 college women between the ages of 14 and 21. While I am by no means convinced that all investigators are correct in their observations and deductions, I am of the opinion that many are right in attacking present educational methods as pernicious to well-rounded physical development, the highest mental attainment and stable nervous equilibrium. That it also predisposes to pulmonary disease and gynecologic troubles, there can be no doubt. Further, it adds its quota to victims of ocular disease. In the school of which I have charge there has been a college physician since its beginning, and every provision has been made for the care of the sick, but we have had many patients who probably could attribute their ill health to their college days, in spite of all our care. If this be true in a college under the daily supervision of a physician, what must be the condition in a college without any supervision?

(*To be continued.*)

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting, held Nov. 19, 1908.

The President, Dr. John A. Wyeth, in the Chair.

Medical Service in a Modern Army in War, as Exemplified by the Japanese Army in the Russo-Japanese War.

Major Charles Lynch, M.D., U. S. Army, delivered this anniversary discourse:

During the Russo-Japanese War I served as military attaché to the legation in Tokio. My service comprised the last ten months of the war, nearly all of which time was spent at the front in Manchuria with the Second Japanese Army.

The reasons that enabled the Japanese to accomplish such noteworthy results may be considered under three heads—organization and administration, sanitation, and professional care of ill and wounded. Any medical department, in order to be efficient, must be sufficient in numbers to perform the work required of it. The Japanese were liberal in providing medical personnel; they found that they required 1 per cent. of medical officers and 9 per cent. of inferior medical personnel to the total fighting force. They recognized that quality was as important as quantity and offered inducements in pay and promotion sufficient to secure good men. The Japanese medical department had complete autonomy, while the Russian had not. The aid given the wounded consisted of regimental aid on the firing line, then at the temporary dressing station, then the dressing station, the field hospital, the transport department for patients, the stationary hospital, the line of communication hospitals, hospital ships, the receiving hospital at home, hospital trains, rest stations, reserve hospitals and convalescent camps. This was the Japanese organization.

At the battle of Mukden, the greatest on record, there being about 310,000 men engaged on either side, the Japanese losses were reported to be about 45,000 killed and wounded. Despite the fact that the battle lasted from March 26 until April 10, and despite the heavy fire of the Russians and the disadvantages of the weather, there were practically no wounded on the Japanese side who were not under shelter within twelve hours, and almost all were cared for in a much shorter time. Japan always provided adequate, though sometimes rough, means for the care of ill and wounded, while Russia provided comfortably at some points and at others left ill and wounded without food or attendance. Japan operated 20 hospital ships, and these were frequently loaded in two days at Dalny and started for Japan. Hiroshima was the principal hospital center in Japan and provided for about 70,000 patients and for 10,000 convalescents in the convalescent camp. These men had every comfort and care which their country could supply. In all previous wars, except the Franco-Prussian on the German side, the death rate from disease was greater than that from wounds. In the field army the Japanese reported 100 deaths from wounds to every 47 deaths from disease. While Russian statistics are worthless on this point, Russia's loss from disease was probably twice that of Japan.

Though the Japanese were generally successful in preventing diseases of known causation or methods of spread, they failed with beriberi. A soldier who returned home to Japan suffering from a preventable disease was made to feel by his family and friends that he was no credit to them or to his country. A commander in the Japanese army whose troops suffered to an unwarranted extent from disease was likely to be called on for an explanation. Personal hygiene was taught in all the schools of the line officers, even in the staff college, the highest officers' postgraduate school in Japan. The soldiers received their instruction from the medical officers of their regiments. Sanitary inspections were made by medical officers of all grades, and consequently sanitary faults could not escape detection and were promptly rectified before serious damage could result. The troops were examined monthly, the unfit weeded out, and communicable diseases promptly dealt with.

The Japanese provided well for the food supply of the army. The standard allowance of food daily was 2,580 calories. The prevalence of beriberi led to the substitution of one-third barley for that amount of rice during the winter of 1904, but so far as had been observed this had no effect on the disease. Practically all the water used by the Japanese was sterilized by one method or another; it was boiled whenever possible.

The habits of the Japanese soldier were good; drunkenness was almost unknown, and successful efforts were made to prevent the soldiers from cohabiting with the Chinese women, among whom venereal disease was common, by appealing to their love for their families and their country. Even in the field the soldiers seldom failed to take a daily hot bath. The Japanese recognized the possibility of infection from flies. As they could not prevent the flies from having access to fecal matter, they served food only immediately before it was to be eaten and covered their dishes immediately after washing them. For the prevention of diarrheal diseases an intestinal antiseptic was issued to the soldiers; this was a creosote pill and was given out in little tin boxes on which was written: "To defeat the Russians, take one pill three times daily." It is believed that this was an error, however. The Japanese might be said to have had one case of typhoid and dysentery to the Russians' six. Typhus, though prevalent in Manchuria, was rare in the army. Tuberculosis was uncommon, smallpox rare and other infectious diseases occurred only in isolated cases. The increase of beriberi during the war might be ascribed to the overcrowding of the barracks and other quarters which gave opportunity for the spread of the disease from man to man. The success attained was due to the practical application of recognized rules of sanitation.

The Japanese, successful as they are as organizers, administrators and sanitarians, can teach Americans nothing in the practice of medicine and surgery. They returned a large percentage of sick and wounded men to the ranks, however. The packet for first aid was too small, badly folded and easily contaminated in handling; later an improvement was made in this respect. The strength of an army is not measured by the number of men on its rolls, but by the number on the firing line. Unless the medical department of an army is so organized and administered the combatants on the firing line are given prompt attention, this line will soon melt away by unhurt men leaving to help their wounded comrades. Both in peace and in war the medical department of an army should guard against unjustifiable loss. The bad organization and administration of the medical department of the Russian army was undoubtedly one of the factors that contributed to its defeat.

If America wishes to profit by the experience of the Japanese we should recognize that we must have a strong framework of medical officers on which to erect a structure fit to bear the strain of war. The efficiency of the army medical department can be secured only by the creation of public interest and sentiment on the subject. In securing good sanitation we have greater difficulties to encounter than the Japanese had. The Japanese recognize that good sanitation depends, to a great extent, on the good teaching of personal hygiene to the individual officers and men. With them this is comparatively easy, as their war army, though far greater than their peace army, is made up from active and reserve lists of the regular establishment only, and all officers and men are consequently well instructed. America, on the other hand, has but a small army in peace which has to be augmented largely by absolutely untrained men, so that if America wishes to rival Japan in low morbidity rates she will have to teach hygiene outside the army. This can be done by good instruction in personal hygiene in the schools. This means the instruction of a people. It will benefit not only the army, but the entire public.

The army medical department in this country has already done much. The military forces are in a state of transition, but they are approaching logical organization. They have been hampered by lack of personnel; but they have succeeded in having passed "A Bill to Increase the Efficiency of the Medical Department of the Army." Since then it has been possible to devote more time in other directions.

Book Notices

INTESTINAL AUTOINTOXICATION. By A. Combe, M.D., Professor of Clinical Pediatry at the University of Lausanne (Switzerland) together with an Appendix on the Lactic Ferments with Particular Reference to Their Application in Intestinal Therapeutics, by Albert Fournier, Formerly Demonstrator at the Sorbonne, Paris. Authorized English Adaptation by William Gaynor States, M.D., Clinical Assistant in Rectal and Intestinal Diseases, New York *Polyclinic.* *Cloth.* Pp. 461, with illustrations. Price, $4.00. New York: Rebman Co., 1908.

An English translation of this book, which has marked a great step in advance in French literature, ought to find a warm welcome in this country. Combe is a past master in the art of dietetic therapeutics, and commands attention even from those who do not accept in full the theory of autointoxication. The object of his book is to make known his methods of treatment, the discussion of which occupies 202 pages, or almost one-half of the text.

The other part of the book is taken up by a detailed consideration of the "scientifically verified theory" of autointoxication, the distinct pathogeny of the condition, its symptomatology and prognosis. Combe limits his study to autointoxications produced by toxic substances derived from albumin. Thus he entirely ignores the results of the important researches of Finkelstein. Furthermore, to him autointoxication is only the toxemia produced by substances decomposed within the body by vital processes of the organism. He eliminates, therefore, all intoxications in which the toxic substances are formed outside of the body and also those in which the decomposition takes place inside the body but through the activity of microbes accidentally introduced from without. Whether the present status of biologic chemistry and our knowledge of the normal intestinal flora permits such sharply drawn limits may be open to discussion. At any rate, the subject to which Combe limits himself gives him sufficient material to fill more than one-half of the book. His chapter on the chemistry of toxic substances derived from the protein molecule is based on the researches of the German school, while in the discussion of experimental pathology he follows almost entirely the work of Charrin and his co-workers. The chapter is full of suggestions and gives a connected account of one of the most disputed topics of internal medicine. Complete reference to the literature, given throughout, ought also to prove stimulating for further research.

In the chapters on symptomatology and diagnosis Combe shows himself the wise observer of the individual case and the results of laboratory analysis. While to Bouchard, the founder of the theory of autointoxication, this was in most cases merely an expression of gastric dilatation, there exists for Combe a wealth of pathognomic symptoms which permit diagnostic interpretation. He is, however, not guilty of making systematized deductions from isolated findings, especially in regard to the excretions, as so many recent authors, the French, in particular, have done. He understands how to weigh critically and to apply individually. The direct observation of the patient himself has not less value than the result of chemical analysis. From this point of view his interpretations of the results of urinalysis are novel and suggestive. Here for positive deductions from the quantitative analysis he calls attention to the necessity of determining not only absolute quantities, but also the ratios between matters excreted. Bouchard's coefficient, stating the ratio between the amount of urea and the total residue, for him still denotes the vitiation of metabolism and insufficiency of nutrition in autointoxication, although he seems to place more diagnostic reliance on his own coefficient, indicating the ratio between aromatic bodies and total nitrogen, as a better measure of intestinal autointoxication.

The chapter on treatment will merit the closest study by American readers. Intestinal antisepsis and medicinal therapeutics in general are put into the secondary position which they undoubtedly deserve. The closest and most detailed attention is given in their stead to the alimentary *régime*. The lucid description of the grape cure little practiced here, the lacto-farinaceous régime, the use of yeasts, and especially of the pure cultures of the bacillus of Massol and the lactic acid bacillus, recommended by Metchnikoff, intestinal lavage and oleoclysms will merit careful study and stimulate useful application. Detailed recipes add very materially to the value of this work.

The translation is good, but by no means perfect. One is frequently shocked by misspelled words which ought to be avoided in a work of such importance. The dipthongs "œ" and "æ" are used with little discrimination; Kühne is Kuhne throughout the book, Homburg is Homberg, hyphomycetes are hypomycetes, lipolytic is lypolyptic, dyscrasic is dycrasic, a tubercle bacillus is a tubercular bacillus. In a revised edition such errors will, of course, be corrected.

Venoms, Venomous Animals and Antivenomous Serum-Therapeutics. By A. Calmette, M.D., Director of the Pasteur Institute, Lille. Translated by Ernest E. Austen, F.Z.S. Cloth. Pp. 403, with illustrations. Price, $5.00. New York: William Wood & Co., 1908.

Our knowledge of the constitution and physiologic action of venoms of various kinds has made great advances during the last fifteen or twenty years. The discoveries of Roux and Behring with respect to the toxins of tetanus and diphtheria immediately turned the attention of certain investigators to the promising field for fruitful work with venoms along the same lines as pursued so successfully in the cases of these bacterial toxins. Pioneer and pre-eminent in this special field of research, Calmette now presents in monographic form the chief results of the modern investigations on venoms, venomous animals and antivenomous serum therapeutics. The book takes up the subjects of the classification, description, distribution and habits of venomous snakes; the clinical and physiologic properties of snake venoms; antivenomous serum therapeutics; venoms in the animal series, and "documents" relating to the treatment of persons and animals with antivenomous sera. There are now special laboratories for the preparation of antivenomous sera in all countries in which venomous snakes constitute a formidable danger to human beings and domestic animals. The volume is rich in illustrations of various kinds of snakes and of the most important portion of their anatomy, the head. The work will be of service to all who are really interested in biologic research and especially so to physicians, travelers, naturalists and teachers in countries where poisonous snakes abound, on whom naturally falls the duty of popularizing information in regard to the new treatment among the indigenous peoples.

The Bone-Marrow. By W. E. Carnegie Dickson, M.D., B.Sc., Edin., F.R.C.P., Edin., Lecturer on Pathologic Bacteriology in University of Edinburgh. Cloth. Pp. 160, with illustrations. Price, $12.00. New York: Longman, Greene & Co., 1908.

This is an elaborate monograph on the structure of the bone-marrow in health and disease, with about 78 pages of text, illustrated with 51 microphotographs and a large series of beautiful water-color drawings covering twelve plates. The illustrations, which merit unstinted praise, are all the work of Mr. Richard Muir, the technician in the pathologic laboratory of the University of Edinburgh. The work consequently is in reality an atlas of normal and pathologic anatomy of the bone-marrow, and as such it will constitute a distinct landmark in the study of this important and generally but poorly understood and neglected tissue. The bone-marrow is the parent tissue of the red corpuscles and also of by far the greater part of the leucocyte series of the formed elements in the blood; therefore, when we consider the extreme readiness with which the marrow and its cellular offspring undergo variations, it is justifiable to assume with Dickson that a closer study of the marrow may throw added light on many phenomena of disease. Modern hematology has given us a number of valuable facts and it is high time that our knowledge of the changes observed in the circulating blood elements in various conditions should be more closely correlated than heretofore with a parallel knowledge of the fundamental changes in the mother tissue. Only in this way may we hope to secure a broader basis for a more penetrating and farther reaching interpretation of the blood changes readily determinable by the methods of blood examinations now so generally in vogue. That generalizations of great clinical importance will be reached as this study progresses can not be doubted. Dickson's work, being essentially morphologic, forms an introduction to the more detailed study of the bone-marrow in special diseases; it gives a good basis on which to start new investigations. Dickson points out there are indications that many diseases now regarded as primary bone lesions, such as osteitis deformans, osteomalacia and osteoporosis, in reality are results of changes in the bone-marrow incidental to reactions on its part to toxic substances introduced or manufactured in other parts of the body. If these diseases come to be looked at from this viewpoint, further investigations into their exact nature may prove more fruitful than the results so far secured. Some of the changes in primary blood diseases—leukemia, pernicious anemia—may also come to be regarded more generally than at present as part of the results of reactive processes in the marrow set in motion by hostile substances. Dickson points out, too, that severe secondary anemias may yet be regarded as the result largely of degeneration in the tissue of the bone-marrow. Destruction of the formed elements of the blood in many acute infectious diseases and other processes may lead to excessive functional activity in the marrow, which in turn undergoes exhaustion and degeneration followed by prolonged anemia. Here further and detailed study are indicated. Dickson's monograph will appeal to hematologists who are interested in the mother tissue of the elements they study so assiduously; and the illustrations are sure to call forth the admiration of all students of the blood and to quicken their wonderment and curiosity in regard to the bone-marrow and the mysterious processes that take place there.

Médicaments Microbiens: Bactériothérapie, Vaccination, Sérothérapie. Par Metchnikoff, Sacquépée, Remlinger, Louis Martin, Vaillard, Dopter, Besredka, Wassermann, Leber, Dujardin-Beaumetz, Salimbeni, Calmette; vol. xi, Bibliothéque de Thérapeutique publiée sous la direction de A. Gilbert et P. Carnot. Cloth. Pp. 400, with illustrations. Price, 8 francs. Paris: Librairie J. B. Baillière et Fils, 1909.

This volume is one of a series of twenty-five intended to constitute a library of therapeutics, and divided into three series, on the subjects, respectively of therapeutic agents, medications and treatments. The present volume deals with the microbic medicaments and covers vaccination, including the prophylactic and therapeutic inoculations of dead bacteria or bacterial products, and serum therapy. There is also a chapter by Metchnikoff on so-called intestinal bacteriotherapy, by which is meant the employment of diverse bacteria in order to antagonize certain possibly pathogenic microbes in the intestine. As the list of authors shows, many representative investigators have contributed to the book. The practicing physician who can read French will find in this volume a very satisfactory statement of the present condition of our knowledge of the subjects with which it deals.

Syphilis Osseuse (Syphilis Acquise). Par Louis Spillmann, Professeur agrégé a la Faculté de médecine de Nancy. Paper. Pp. 134, with illustrations. Price, $0.85. Paris: G. Steinheil, 1909.

In this treatise the author has left out of account lesions of the bones indirectly attributable to syphilis and has devoted himself to lesions of the bones, which are syphilitic by nature as well as by origin. The first four chapters consider history, etiology, and pathology, while the fifth is devoted to clinical studies of the syphilitic affections of the different bones. Diagnosis and treatment are then taken up. The book was produced under the inspiration of Professor Fournier, whose personal notes and collection of specimens Spillmann has been able to make use of. The twelve plates added at the end of the volume form in themselves a valuable collection of illustrations not hitherto published.

Tuberculosis in Massachusetts. Prepared by the Massachusetts State Committee for the International Congress on Tuberculosis, held at Washington, D. C., September, 1908. Edited by Edwin A. Locke, A.M., M.D. Cloth. Pp. 223, with illustrations. Price, Wright & Potter Co., 1908.

This volume was prepared by the Massachusetts State Committee for the last International Congress on Tuberculosis, as a supplement to the general exhibition presented at that congress. It includes an account of the work of the State Board of Health, state inspectors, communities and antituberculosis societies, together with a discussion of bovine tuberculosis, tuberculosis among the insane, among prisoners and industry, and a number of related topics. The book is well illustrated and presents a mass of information of great value to those interested in the subject of the prevention of tuberculosis.

Text-Book of Nervous Diseases and Psychiatry. By Charles L. Dana, A.M., M.D., LL.D. Professor of Nervous Diseases in Cornell University Medical College. Seventh edition. Cloth. Pp. 782, with illustrations. Price, $5.00. New York: William Wood & Co., 1908.

This edition differs little from its predecessors. It has been thoroughly revised and brought up to date, and additions have been made to the sections on histology of the neuron and on anatomy and physiology of the brain, the works of Sherrington, Grünbaum, Campbell and Horsley having made this necessary. A short chapter has been added on psychotherapy, but the subject deserves more attention than Dana has given it here. The chapters on neurasthenia and hysteria have been rewritten, and under the name "psychasthenia" is described the condition designated "phrenasthenia" in the previous edition. Obsolete matter has been deleted, so that the book is not materially enlarged.

Emergency Surgery. By John W. Sluss, A.M., M.D., Professor of Anatomy, Indiana University School of Medicine. Flexible Leather. Pp. 692, with illustrations. Price, $3.50. Philadelphia: P. Blakiston's Son & Co., 1908.

This is one of a leather-bound series of medical manuals and is of convenient size and shape to carry in one's pocket. It is well bound in flexible leather, copiously illustrated and printed on a good quality of paper. Without attempting to cover the general field of surgery, Dr. Sluss discusses the emergencies which the general practitioner is most apt to encounter. The works of Senn, Walshan, Treeves, Legar, Veau and von Bergmann have been copiously utilized. Many references to current surgical literature also appear. The book will prove of value to general practitioners who are compelled to do a certain amount of emergency work.

Diseases of the Nose and Throat. By Cornelius Godfrey Coakley, A.M., M.D., Professor of Laryngology in the University and Bellevue Hospital Medical College, New York City. Fourth Edition. Cloth. Pp. 604, with illustrations. Price, $2.75. Philadelphia: Lea & Febiger, 1908.

This edition is essentially like the preceding ones, except that it contains a chapter devoted to formulas which will be found convenient for the practitioner. Dr. Coakley treats his subject concisely and clearly and describes all the principal diseases of the nose and throat. The book is illustrated by 126 engravings, mostly taken from various well-known authors, and seven colored plates, those illustrating transillumination of the accessory sinuses being very good.

Aids to Tropical Medicine. By Gilbert E. Brooke, M.A., Cantab., L.R.C.P. Edin., D.P.H., F.R.G.S., Port Health Officer, Singapore. Cloth. Pp. 163, with illustrations. Price, $1.00. New York: William Wood & Co., 1908.

This is a good synopsis of what is known of the diseases of tropical countries, and will furnish information to those who wish an outline of those diseases, which, while frequently mentioned in current medical literature, are seldom seen in temperate climates. It contains an appendix in which is given the regulations of examining boards for diplomas in tropical medicine, such as are awarded by the universities of Great Britain.

Student's Handbook of Gynecology. By George Ernest Herman, M.D. (Lond.), F.R.C.P., F.R.C.S., Consulting Obstetric Physician to the London Hospital. Cloth. Pp. 544 with illustrations. Price, $2.50. New York: William Wood & Co., 1908.

In this book Herman has endeavored, by omitting explanatory, argumentative and speculative matter, references to rare cases, and descriptions of the less commonly performed operations, to condense his larger work and to present a small volume especially for students. The result is a volume of 535 pages, closely printed on thin paper, adequately illustrated and excellently arranged. It supplies concise information, without being that bane of the American medical school, the quiz-compend.

General Pathology. By Ernest Ziegler, Professor of Pathologic Anatomy and of General Pathology in the University of Freiburg in Breisgau. Translated from the Eleventh German Edition (Gustav Fischer, Jena, 1905). Edited and Brought up to Date by Alfred Scott Warthin, Ph.D., M.D., Professor of Pathology and Director of Pathologic Laboratory in the University of Michigan, Ann Arbor. Cloth. Pp. 781, with illustrations. Price, $5.50. New York: William Wood & Co., 1908.

Among text-books which may be regarded as authorities in medicine, that of Ziegler has reached a very high position. Ziegler's genius and industry were devoted to perfecting this book and keeping it abreast of the advance of knowledge. It was so successful that it reached the eleventh edition before Ziegler's death. In the present translation, edited and brought up to date by Dr. Warthin, it forms a work worthy of commendation. Although the German edition was written in 1904, the intervening years have produced so much investigation on so many subjects as to necessitate the interpolation of a large number of paragraphs in fine print, presenting the most recent results of work in pathology. The translation is well done; the illustrations are numerous and especially clear. A number of them consist of colored plates.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

Success in Postgraduate Work.

The Rapides Parish (Louisiana) Medical Society reports that it took up the postgraduate course of study last May and has met regularly every Monday night since the work was begun. The secretary, Dr. J. L. Wilson, says:

> "The course of study has entailed on us a great deal of work, but we started out fully determined to keep up with it and we have done so. Recently our president asked Dr. Edmond Souchon, late professor of anatomy of the Medical Department of Tulane University at New Orleans, to furnish us with some anatomic specimens or dissections preserved with his special formula for preserving the muscles and tissues in their natural color. The doctor first wrote us that he would be unable to do so; a few days later, however, he wrote us that he had decided to preserve a subject, send it to us, and come himself, remain with us for a few days, and assist us by giving us demonstrations in surgical anatomy. We profited very much by Dr. Souchon's visit and the members of our society are under lasting and grateful obligations for his interest. We all feel that we have been greatly benefited by the postgraduate course. Every county society would be greatly benefited by taking up this study course. The visit of Dr. McCormack to our state and city was a great stimulus for us. His lectures were an inspiration to the members of the profession such as we have seldom received, and I am sure all those who heard him profited thereby."

Optometry in Drugstores.

The *Ohio State Medical Journal*, in its department of Medical Economics, November, discusses some phases of the optometry bills which have been introduced in various state legislatures and presents a new phase of the question. A Cleveland physician received an announcement from a local pharmacy stating that it carried a complete line of drugs, medicines, optical goods and drug sundries. The physician at once wrote to the druggist severing all business relations with him and adding: "It is bad enough that department stores maintain quack optical departments to the further detriment of human eyes. Drugstores at least have no excuse for entering this field." The editor of the department of economics, in commenting on the incident, says:

> "The optometry bill would give legal recognition and professional standing to this sort of imposition on the public confidence; it would establish false relations with medical standards and false assurance with the public. Without stultifying itself, the state can not establish two standards in the same branch of medicine. This bill (the optometry bill) puts a full-fledged physician with years of preparatory and scientific study and final qualification before the state medical board against a tradesman with six weeks of special study. . . . The state can not, in fairness to the profession or in the interests of the laity, lower present standards in ophthalmology. Nor will it do so if the legislator is properly instructed."

The persistent efforts that have been made along this line in the past two years should be carefully noted and understood by all physicians, especially by those interested in medical legislation or those making a specialty of diseases of the eye. In several states the endorsement of unthinking physicians or of sections on ophthalmology has been secured for such legislation, under the specious plea of protection of the public from "incompetent optometrists." (God save the mark!) There is no more reason why the state should protect the public against incompetent spectacle fitters than there is why it should examine and license manufacturers of crutches. The only object of such legislation is to give the "graduate" of some "college of optometry" who has enjoyed the inestimable advantages of a six weeks course of instruction, the privilege of hanging a handsomely engraved certificate of license in his shop window and thereby make the public believe that he has the endorsement of the state. Cults and isms heretofore have sprung up around methods of treatment. This fad seems to have developed around a single organ. If a milkman or a drygoods clerk can learn to treat diseases of the eye in six weeks there is no reason why he can not learn to treat diseases of the stomach or of the lungs in the same time. In fact, there is no reason why he could not select the particular organ of the body which seems especially attractive to him and disregard the parts of the body which he does not care to treat.

The whole proposition reduces itself to an absurdity and its ridiculousness should be impressed on the members of our legislatures so as to put a stop to such farcical legislation.

Department of Public Health—Women Take Action.

The Utah Federation of Women's Clubs, at its recent annual meeting at Provo, Utah, adopted resolutions approving the "proposed segregation, concentration, reference and transfer to one department of all matters or questions arising out of or relating to public health and sanitation."

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR. JOHN H. BLACKBURN, DIRECTOR.
Bowling Green, Kentucky.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fourth Month—Fourth Weekly Meeting.

Dislocations of the Ribs.

Ribs.—1. Costo-vertebral, pathology, complications, diagnosis.
2. Costo-sternal, first seven ribs, diagnosis, treatment.
3. Costo-costal, eighth, ninth and tenth, causes, treatment.

Dislocations of Hip and Knee.

Hip.—1. Backward.—(a) Dorsal, iliac or ischiatic: direction of violence, injury to capsule, to ligamentum teres, rim of acetabulum, sciatic nerve, gluteal vessels, quadratus femoris, pyriformis and obturator. Diagnosis, adduction and flexion, inward rotation, shortening, trochanter. Treatment. Smith's manipulation (Bigelow). Stimson's method. (b) Everted dorsal. 2. Downward and Inward—(a) Obturator: Pathology, diagnosis, treatment. (b) Perineal: Differs from obturator, diagnosis. 3. Upward and Forward.—Suprapubic: Iliopectineal or pubic forms, central; diagnosis, method of reduction. 4. Upward (Supracotyloid or subspinous). 5. Downward (Infracotyloid).

Knee.—1. Forward. 2. Backward. 3. Lateral (inward or outward). 4. Dislocation by rotation. Diagnosis, complications, treatment.

Patella.—1. Outward. 2. Inward. 3. Vertical.

Dislocations of Ankle and Foot.

Ankle.—1. Sagittal.—(a) Backward:: Causes, pathology. (b) Forward: Diagnosis, pathology, treatment. 2. Lateral.—(a) Outward: Pathology, diagnosis, treatment. (b) Inward: Pathology, diagnosis.

Tarsal Bones.—Subastragaloid.—(a) Inward, (b) outward, (c) backward, (d) forward: Relations of astragalus, os calcis and scaphoid, and diagnosis in each form.

Metatarsals and Phalanges.

Monthly Meeting.

Diagnosis and Differentiation of Dislocations of Hip Joint.
Treatment of Tuberculosis of the Joints.
Diagnosis and Treatment of Complicated Dislocations.

Medicolegal

Various Points Concerning Insane Delusions and Demand of Change in Declaration as to Monomania.

The Supreme Court of Arkansas says, in Taylor vs. McClintock, that the test of testamentary capacity is necessarily the same, whether the insanity be attributable to dementia or insane delusion—paranoia. "Paranoia" is a term used by medical experts, alienists, and authors on medical jurisprudence to designate the form of insanity characterized by systematized delusions. A systematized delusion is one based on a false premise, pursued by a logical process of reasoning to an insane conclusion. There is one central delusion, around which other aberrations of the mind converge. The term "paranoia" takes the place of the "monomania" or "partial insanity," and includes all that was formerly meant by that word, but is considered a more accurate term to describe the peculiar form of delusional insanity.

It is unquestionably true that one may be possessed of a delusion concerning one subject, and yet be of sound mind on all other subjects, according to the weight of modern authority.

This delusion, which operates to defeat a will made under its influence, may be defined as follows: Where one conceives something extravagant and believes it as a fact, when in reality it has no existence, but is purely a product of the imagination, and where such belief is so persistent and permanent that the one who entertains it can not be convinced by any evidence or argument to the contrary, such a one is possessed of an insane delusion. The above is substantially the definition of Sir John Nichol in 1826 in the great case of Dew vs. Clark, 3 Add. Ecc. 79, and it is one that has been approved and followed by a majority of cases and text-writers ever since.

A delusion can not be predicated on any purely esoteric and abstract subject, for the reason that beliefs concerning such subjects are speculative, and could not be proved false.

Evidence is the means by which facts are proved. All evidence must be addressed to the sane mind. That which no sane mind would believe at all does not rise to the dignity of evidence; and a belief in something that no sane man could believe is evidence of insanity.

Evidence, in a legal sense, is external. It is brought into the mind through the senses, by the mental faculty of perception, and appropriated by the faculty of reason. Therefore, any evidence will produce some sort of impression or belief in the mind, correct or incorrect. It is a solecism to speak of a belief that is based on any evidence as an insane belief or delusion. A belief grounded on evidence, however slight, necessarily involves the exercise of the mental faculties of perception and reason; and where this is the case, no matter how imperfect the reasoning process may be, or how erroneous the conclusion reached, it is not an insane delusion. The legal requirements of a delusion were not met by the testimony of medical experts defining a delusion as "a belief, an idea, held by a person against such ordinary average information or experience as would to the ordinary average individual prove sufficient to cause him to give up the idea."

But not only were there apparently votes lacking to make the court hold, but Chief Justice Hill and Justice Battle protested against holding, that, as a matter of law, a person may be entirely sound mentally on all subjects or as to all individuals save one, and as to that particular subject or individual his mind may be so diseased as to render it impossible to say that he is of sound mind and is capable of reasoning and exercising a sound judgment in regard to the delusion.

This division of insanity into partial and total originated, judicially, the Chief Justice says, with Sir Matthew Hale, when Lord Chief Justice of England in the reign of Charles II. This great jurist did much for the laws of England, yet was not sufficiently beyond his generation to enforce the law against witchcraft (he was the last English judge before whom a person was convicted and sentenced to death for witchcraft). Still his division of sanity is followed by many courts and many alienists.

In view of the disagreement between learned doctors, it is not the province of the court to side with either. It is not a legal question; but the question of insanity is a question of fact, and the learned doctors may explain it in their own way according to their own theories to the satisfaction or dissatisfaction of the jury, but still the question remains with the jury to decide whether the particular person was sane or insane.

When scientists are agreed on these questions, it may be well for the courts to state the scientific conclusion; but when scientists are at large on it, it is not the province of the court to accept either theory, but to leave it, as all other questions of fact, to be determined in the particular instance. In the cases in this and other courts cited in the other opinion in this case, the scientific and legal definitions were accepted without question; but the evidence in this case showed, or tended to show, that the scientific world, or an important part of it, has departed from those theories, and the courts should not blindly follow precedents based on other data.

Claims of Special Surgeons Called in to Operate on Unconscious Fatally Injured Person.

The Supreme Court of Washington says that the plaintiffs in the case of Cunningham and another vs. Lakin were physicians and surgeons, of Spokane, who sued the estate of one Lakin for professional services rendered him during his last illness. It appeared that Lakin had been kicked in the head by a horse, sustaining fractures of various bones of the face and skull and severe injuries to the brain, from which he was rendered unconscious, in which condition he remained until several hours after being operated on by the plaintiffs.

An employé of Lakin who was assisting him in the work he was performing at the time he received said injuries, called a local physician who found that the only hope of saving the life of Lakin lay in a major surgical operation, could not procure the necessary equipment at any nearer place than Spokane, and he would require the assistance of skilful surgeons in the operation. All this he informed the nearest living relative of said Lakin, who was then assuming to represent him and had assumed charge of the management of his affairs. Then, being told to procure the services of skilful surgeons, and to have the operation performed, and to have rendered such professional services, care and treatment as might be deemed most expedient, said physician summoned the plaintiffs, who performed said operation and treated Mr. Lakin until his death.

The objection was raised that no contract of employment on the part of Lakin was shown for the services by the physicians, and no subsequent ratification or agreement to pay on his part after the services had been rendered. The Supreme Court concedes this, but holds that the right of the physicians to recover for the reasonable value of their services, under circumstances such as were shown here, does not rest on any contract with the injured person, either express or implied, but is recoverable by virtue of the statute. Services of the character here rendered are classed as expenses of the last sickness, and are given a preference right of payment over all ordinary debts out of the estate of the decedent. It is true that services of this character differ from administration and funeral charges, in that they are rendered during the life of the person on whose estate they are made a charge, but the necessity for their rendition is similar to that of the latter, and the law authorizing their payment can be justified on like principles.

Whether the charges made by the surgeons were reasonable was a question to be determined from the evidence.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Medical Record, New York.

November 21.

1 *Possibility of Avoiding Conspicuous Scar Formation in Softened Tuberculosis of the Cervical Glands. W. Meyer, New York.
2 *Obstinate Vomiting, or the Personally Conducted Baby. W. P. Northrup, New York.
3 *Endothelioma of the Pleura. H. B. Delatour, Brooklyn, N. Y.
4 Locomotor Ataxia: A New Theory and Treatment, with Cases. L. N. Denslow, New York.
5 Pancreatitis: With Illustration of Crystals of Pancreatic Reaction, According to Cammidge's Test. M. R. Barker, Chicago.
6 Three Unusual Cases of Appendicitis. C. W. Trueheart, Galveston, Tex.
7 Malaria on the Isthmus of Panama. W. E. Deeks, Panama.

1. Tuberculous Cervical Glands.—Meyer praises Bier's method as a means of avoiding scars. The rubber bandage is worn 11 out of 12 hours and fluctuation watched and encouraged. A short cut is then made in the course of the neck fold. If muscle or fat overlaps the incision a small drain is introduced for from 24 to 30 hours. Otherwise the wound is left open and suction treatment started from 4 to 6 hours later by the cups which are used once daily for 45 minutes. Packings and injections are never used.

2. Obstinate Vomiting.—Northrup describes a case that leads to the following conclusions:

1. A nursing baby may vomit because its food enters the stomach too rapidly and consequently in too great quantities.
2. The cause of this overdistention may be sought in the large quantity of breast-milk, easy flow, large nipples, vigorous nursing.
3. The above conditions may be overcome by imposing mechanical obstructions, "drinking up-hill," being here suggested.

In the reported case, the successful position was, sprawling head downward and face downward over the mother's shoulder to the nipple, like a squirrel coming down a tree.

New York Medical Journal.

November 21.

8 *Nature of Carcinoma in General, and the Early Diagnosis of Gastric Carcinoma. J. M. Anders, Philadelphia.
9 Iron (continued). J. Knott, Dublin, Ire.
10 Four Hundred and Twenty-two Cases of a General Surgical Nature from the Surgical Service of Fordham Hospital. A. Nicoll, New York.
11 *Lipoma of the Kidney. O. W. H. Mitchell, Columbia, Mo.
12 *Study of Spores Developed at an Elevated Temperature. B. R. LeRoy, Athens, Ohio.
13 *Pulsation of Large Aneurisms, Nonexpansile, but Transmitted. S. Lange, Cincinnati.
14 An Adjustable Lens for Oblique Illumination of the Eyes. S. W. Newmayer, Philadelphia.

8. Abstracted in The Journal, Oct. 31, 1908, p. 1541.

11. Lipoma of the Kidney.—Mitchell says that as regards the etiology all the following views appear plausible, and in a broad classification should be included until proved to the contrary:

1. The congenital tumors may develop, (a) from fat with imbedded portions of the adrenal; (b) from fat at the hilum; (c) by metaplasia of connective tissue.
2. The acquired tumors may develop, (a) by metaplasia of the connective tissue; (b) by extension of fat tissue from the hilum into the interstitial tissue of the kidney. The last view (2,*b*) seems plausible, since the kidneys of fattened domestic animals show this condition to be present frequently.

12. Spores Developed at High Temperature.—LeRoy's paper is an answer to inquiries concerning his paper on "Etiology of Psoriasis" (*New York Medical Journal*, April 25, abstracted in The Journal, May 9, 1908, p. 1560). In it he describes the growth and development, motion, changes of form, etc., of the organism therein referred to. He adds that the first patient mentioned in his former article is now almost free from psoriatic eruption and he feels confident that he will be permanently cured.

13. Aneurism.—Lange points out that expansile pulsation is laid down in text books as an almost infallible pathognomonic sign of aneurism. He endeavors to show that an aneurism which is large enough to impinge on and impart its pulsation to the chest wall will not, as a rule, execute expansile pulsations, but will simply transmit pulsations from the blood current passing through it, or more often from the heart. The smaller aneurisms do execute expansile pulsations, but the pulsation disappears as the result of the accumulating clot, before the tumor is large enough to impinge on the chest wall and manifest its characteristic pulsations to the palpating hand.

Boston Medical and Surgical Journal.

November 19.

15 *Acute Gonorrheal Epididymitis; Operative Treatment. J. H. Cunningham, Boston.
16 *The Law and Medical Experts; Codes of Criminal Procedure of European Countries. C. G. Cumston, Boston.
17 Bursitis Subacromialis, or Periarthritis of the Shoulder-Joint. (Subdeltoid Bursitis) (Continued). E. A. Codman, Boston.

15. **Acute Gonorrheal Epididymitis.**—Cunningham discusses the etiology and characteristics of this condition, its pathology, prognosis, and symptomatology. He describes the usual method of treatment and urges operative interference, which, he says, brings the suffering to abrupt ending, arrests the acute process, and shortens the duration and the convalescence. It is simply applying the general surgical principle of drainage to the infected organ. He describes Hagner's technic, which essentially consists of a two-inch incision at the junction of epididymis and testicle, the opening of the tunica vaginalis and puncture of the epididymis with a sharp-pointed knife. If pus escapes the opening should be enlarged and washed out with a 1 to 1,000 solution of corrosive sublimate, followed by salt solution. A cigarette drain is used. A continuous catgut suture closes the tunica vaginalis and a lockstitch horsehair suture the scrotal skin. Moist bichlorid of mercury dressings and a scrotal support to testicle complete the process.

16. **Law and Medical Experts.**—Cumston discusses a recent criminal case in New York and summarizes the French, Austrian, Belgian, German and Spanish laws in relation to medical expert work.

Northwestern Lancet, Minneapolis.

November 15.

18 *Present Management of Smallpox in Minnesota. H. M. Bracken, St. Paul.
19 Course of Instruction for Sanitarians and Sanitary Inspectors. F. F. Wesbrook, Minneapolis.
20 Present Status of Smallpox in Minnesota. G. W. McIntyre, St. Peter, Minn.
21 Tuberculosis and Poverty. E. T. Lies, Minneapolis.

18. **Smallpox in Minnesota.**—Bracken recounts the steps which led up to the recent health ordinance in Minnesota, abolishing quarantine in smallpox and relying solely on vaccination. The ordinance came into effect in the midst of an epidemic of a mild type of smallpox. While the number of cases did increase during the first four months after the new regulations went into effect, the statistics of Minneapolis, St. Paul and Duluth, which remained under the old régime, made no better showing in the morbidity rates than the state did under the new regulations, so that the increase can not properly be attributed to them. In consequence of the objections raised by the health commissioner of Chicago the latter was asked to advise the Minnesota state board of all smallpox infections reaching Chicago from Minnesota. This was done, and three cases were reported, but inasmuch as one came from St. Paul and one from Duluth, which were under the old regulations, the new regulations for the state could not be held responsible. Bracken analyzes the sources of imported smallpox infections in Chicago, from January 1 to July 25, 1908. They numbered 36, one of which was from a district of Minnesota under the new regulations, and 35 from cities or states still practicing rigid quarantine for smallpox. Chicago, with its 47 infections, is also supposed to be under rigid quarantine supervision. The plan adopted by Minnesota has been followed by North Dakota, and is now under consideration by one of the western Canadian provinces and one of our western states; the latter case in a more radical form than that existing in Minnesota. The article concludes as follows: "On deliberate consideration of conditions the Minnesota State Board of Health feels that it has made no mistake in its new regulations unless it is that they are not sufficiently radical."

27 *Diagnosis of Duodenal Ulcer. B. G. A. Moynihan, Leeds, England.
28 Broad Ligament Plication for Uterine Retroversion. C. N. Suttner, Walla Walla, Wash.
29 Primary Implantation of an Ovum in the Pelvic Peritoneum. B. C. Hirst and N. Knipe, Philadelphia.
30 Primary Carcinoma of the Body of the Uterus. C. N. Ballard, Chicago.
31 *Immediate vs. Deferred Operation for Intra-abdominal Hemorrhage Due to Tubal Pregnancy. F. Krug, New York.
32 Puerperal Salpingitis. L. V. Friedman, Boston.
33 Delivery of the Fetal Head After Decapitation. J. C. H. Leicester, Calcutta, India.
34 Radical Operation for Cure of Oblique Inguinal Hernia. F. G. Connell, Oshkosh, Wis.

22. **Retrodisplacements of the Uterus.**—Coffey's paper is an elaborate study illustrated with colored plates and half tones. He arrives at the following conclusions: The ideal operation for retrodisplacements of the uterus consists in some form of operation which shortens the anterior fold of the broad ligament, at the same time temporarily utilizing the round ligament for its accompanying connective tissue, but which uses absorbable sutures and thus makes provision for complete recovery of the position and function of the round ligaments as soon as the sutures are absorbed.

23. **Ventrifixation.**—Alexander has never performed either ventrifixation or ventrosuspension, because he believes that all such operations are fundamentally opposed to Nature's plan. His *a priori* objections have been confirmed by numerous reports of serious results, and he has had within a few weeks of each other two patients in his clinic on whom such operations have been performed, and in whom such a distressful condition existed that the uterus had to be released. This afforded a full opportunity for seeing the anatomic, as well as the clinical, results of the operation. He reports the cases. In the first, a patient, the subject of some prolapse without other symptoms, was rendered miserable after operaiton by incontinence of urine and constant pain, far more serious troubles than she had previously suffered from. On operating Alexander found the internal relations of the pelvic organs entirely changed. The uterus hung awkwardly from the abdominal wall, with the fundus projecting backward, as an obstacle against which the intestines could beat, and the great omentum had numerous adhesions to the various parts in the neighborhood of the old scar. The corpus uteri was changed into a long cord. When the adhesions were removed and the round ligaments curtailed, the uterus assumed rapidly its normal shape, the symptoms disappearing as if by magic. A similar condition of things obtained in the second case. Alexander holds that for retroflexion the treatment most in accord with the economy of Nature is to straighten out the uterus to a natural shape and shorten the round ligaments externally. He maintains also, from his own practical experience, that the shortening of the round ligaments in prolapse, when associated with repair or advancement of the perineum, is permanently effectual even in very bad cases. He describes his procedure and gives the reasons why the method is so effective.

25. **Hebosteotomy.**—Pfannenstiel is convinced that hebosteotomy is a great advance in obstetrics, and that with proper technic and observance of indications, and without increased danger to the mother, we shall succeed in securing a considerable percentage of children that were lost by former methods of delivery.

27. **Duodenal Ulcer.**—Moynihan arrives at conclusions, of which the following is a summary:

1. The operative treatment of stomach disorders should be confined exclusively to those cases in which an organic lesion is present.

2. In cases of acute perforating ulcer, the perforation should be closed or the ulcer excised.

3. When a non-malignant lesion is discovered, the treatment appropriate to it depends on its position in the stomach.

4. If the ulcer be prepyloric or duodenal, gastroenterostomy should be performed.

5. The most satisfactory method of [illegible] posterior no-loop operation, with the al[illegible] of the bowels to the stomach.

6. Regurgitant vomiting occurs as a result of the "loop" operation, whether anterior or posterior. It is relieved almost certainly by an enteroanastomosis.

7. In cases of hour-glass stomach the surgical treatment necessary presents special difficulties on account of the frequency of a dual lesion.

He epitomizes as follows the surgery of benign disorders of the stomach and duodenum: In cases in which genuine organic disease of the stomach or duodenum has been present, and that treatment which his present experience would indicate as appropriate has been adopted, surgical measures have been attended with a small mortality, and the relief afforded has been complete and permanent. In cases in which the evidence of structural disease was insignificant or absent, the result has been indifferent or positively bad. The scope of such operations as Rodman's, the excision of the ulcer-bearing area, and of the excision of ulcers on the lesser curvature and toward the cardia, should unquestionably be broadened. Moynihan has been in error in several cases in resorting to gastroenterostomy instead of to the more radical and perhaps equally safe procedures.

36. Abstracted in The Journal, May 30, 1908, p. 1819.

41. **Adams-Stokes Disease.**—Beck and Stokes describe a case, which they illustrate with half tones and colored plates. The character of the attacks did not vary much, except in degree. Some were apparently much more severe than others. They were usually preceded by a distinct aura, which was in the form of sounds resembling the ringing of bells or music. This was associated with intense pain in the right side of the head and face. There were also spasmodic contractions of the muscles in this area. During this stage, the patient rose up in bed, grasped the right side of the face with the right hand and groaned. He soon afterward sank into unconsciousness, which lasted five to fifteen seconds. During this period the color of the face was an ashen gray; the lips were cyanotic and the breathing was slow, irregular, and stertorous. After returning to consciousness, the patient sank his head into the pillow and lay exhausted, with beads of perspiration on the face and extremities. In all the earlier attacks and the minor attacks during the course of the disease, unconsciousness was not complete and the other symptoms were not so marked. A record taken shortly after a series of seizures with syncope and convulsive movements shows a brief stoppage of the ventricles without any other associated phenomena. The tracing shows distinctly the acceleration of the auricular beat with a diminished contraction, a condition which usually precedes a ventricular pause. During the stage in which the auricular impulse was feeble, the ventricles contracted independently of the auricles, causing complete heart block. Finally, when the auricular rhythm became more regular and the force of the contraction stronger, every other beat stimulated the ventricles to contraction, thus producing a 2:1 rhythm. At autopsy it was found that the primary lesion in this case consisted in marked calcareous infiltration of the auriculoventricular groove and its surrounding muscular and fibrous tissue. This produced pressure on the bundle of His, causing extensive fibrous myocarditis with atrophy of the muscular fibers. These conditions must have interfered with the normal transmission of the muscular impulse from the auricles to the ventricles, thus producing the symptoms described in the paper.

50 Multiple Pregnancies in Double Uteri, with Report of Case of Uterus Didelphys Containing a Simultaneous Full Term Pregnancy in Each Uterus. C. F. Jellinghaus, New York.

45. **Ectromelia.**—Kosmak reports, with an illustration, a case showing entire absence of the upper extremities. The left eye is represented merely by a small hard globular mass. There is no upper lip, not a dimple indicating where the arms ought to appear on the shoulder-girdle; also other deformities. The author assumes that in this case we are dealing with an instance in which a lack of germinal substance is probably the etiologic factor in the production of the deformities.

48. **Artificial Respiration in the New-Born.**—Morgan points out that the methods of resuscitating new-born infants are by no means free from danger, if indiscriminately or carelessly used. He reports cases. He describes what he considers a very satisfactory method of treating asphyxia in the new-born. After delivery of breech the child should be immediately inverted and held in that position until respiration becomes deep and regular. If there is any evidence of foreign material in the throat the pharynx should be gently stripped in the direction of the chin, the oropharynx swabbed with gauze or wet cotton, and the contents of the nose squeezed out. Catheterization of the larynx is rarely necessary. A few sharp slaps on the buttocks will usually aid the desired result. If the condition is more serious, as evidenced by the general cyanosed appearance of the child and by the diminished heart action, which can be most readily ascertained by placing the finger on the cord, it should be separated from the placenta in order that the movements may be less restricted. The child must be kept warm constantly by immersing in hot water or wrapping in hot towels. While in the tub, Sylvester's method may be resorted to. Removing the child at intervals and sprinkling its body with cold water, powerfully stimulates respiration.' Mouth to mouth insufflation may be practised by resting the back of the neck on the edge of the tub and supporting the head with one hand, while pressing on the epigastrium with the other. Only the first of the expired air is to be used and the nose should not be compressed but left entirely open, in order that there may be free passage for any excess of air injected. Laborde's method may be used by an assistant at this time. The hypodermic injection of ether, camphor or whisky is beneficial at times.

54 *Variability in the Diphtheria Group of Bacilli. H. M. Goodman, Chicago.

55 *Resistance of Embryonic Epithelium, Transplantable Mouse Cancer, and Certain Organisms, to Freezing with Liquid Air. H. R. Gaylord, Buffalo, N. Y.
56 *Chemistry of Anaphylaxis. H. G. Wells, Chicago.

51. **Multiplication of Bacillus Coli.**—By an ingenious method Barber has studied the reproduction rate at different temperatures of the colon bacillus. Reproduction begins at about 10° C., increasing rapidly to about 37°, where it reaches its maximum rate, with a generation time of 17 minutes. It maintains this rate nearly constantly until the temperature reaches 45°, when the rate falls rapidly. Hence it is not probable that any temperature of the body during fever is of itself high enough materially to affect the reproductive rate of pathogenic bacteria, at least not that of the colon bacillus.

52. **Agglutination of Glanders Bacillus.**—Collins concludes that positive agglutination of the glanders bacillus by horse serum in dilution of 1 to 1,000 indicates latent or active infection of the horse furnishing the serum; while in human cases agglutination with dilutions above 1 to 100 would undoubtedly indicate glanders.

53. **Determining the Bacterial Content of Milk.**—Heinemann and Glenn emphasize the fact that the bacteriologic and chemical examination of milk should be conducted with the special object of improving the whole milk supply of a community, and that naturally for this purpose the most accurate, scientific methods of examination are to be used. The article indicates certain improvements on the previous bacteriologic methods of milk examination.

54. **Variability of Diphtheria Bacilli.**—From extensive experiments Goodman reaches the result that the division of the diphtheria group of bacilli into several different species is probably not warranted and that all the forms that have been described under different names are simply variants of a single species, *Bacillus diphtheriæ*.

55. Commented on editorially in THE JOURNAL, Nov. 14, 1908, p. 1701.

56. **Anaphylaxis.**—Wells has studied certain phases of the chemistry of hypersusceptibility. He finds that egg albumin freed from other proteins of egg white sensitizes in doses as small as 1/20 of a millionth of a gram, fatally in doses of one millionth of a gram, and that the minimum lethal dose for sensitized pigs is about ½ a miligram, by intraperitoneal injections, and from 1/10 to 1/20 milligram when injected into the circulation. When so small a quantity of egg albumin is fatal to sensitized pigs he thinks it improbable that the injected protein itself causes death by liberating toxic substances on being split up. He regards it as more probable that if poisonous substances are produced they come from the cells of the intoxicated animal, or possibly the whole reaction may be different from ordinary intoxication. The minuteness of the sensitizing and intoxicating doses of pure albumin indicates further that in this particular protein the two agents, the sensitizing and the intoxicating, are either one and the same or different portions of the same molecules.

57. **Adenoids.**—Savage discusses this condition, and, as regards treatment, holds that the curette and forceps, and even the finger, are not worthy of comparison with the Gradle adenotome. He describes the method of its use.

61. **Malarial Purpura Hemorrhagica.**—Deaderick remarks on the rarity of purpuric eruptions associated with genuine hemorrhages in malaria, and reports the case of a white woman who lived on a shanty boat in eastern Arkansas for three years. In the summer of 1907, during a series of chills, purpuric spots appeared all over the body, and hemorrhages occurred from the mouth and nose. The treatment consisted of a teaspoonful every four hours of an elixir containing 5 grains of calcium chlorid to the dram, besides an antimalarial tonic of strychnin, arsenic, iron and quinin. In two months she was practically well (though the spleen was still considerably enlarged) and has had no chills or purpuric symptoms up to date, the longest interval free from chills that she has enjoyed for several years.

68. **Fracture of Shaft of Femur.**—Huntington reports three cases treated by the open method, that is, by stapling, or "the internal splint," as advocated in the paper by him (*Annals of Surgery*, September, 1908: abstracted in THE JOURNAL, Oct. 17, 1908, p. 1373) and reproduces what are practically the same conclusions. In this article he emphasizes the value of pulley traction in the adjustment of fractures during operation.

70. Published in the *Virginia Medical Semi-Monthly*, Oct. 9, 1908.

71. **Hysteria.**—Williams reports a case, in order to emphasize the importance of recognizing and appropriately treating manifestations which are very common. It shows the efficacy of skilfully conducted suggestion; but the length and difficulty of the treatment of the morale showed that the removal of symptoms is but palliative, and that the true psychotherapy of hysteria consists of the uprooting of the habits of mind due to faulty education, and in the replacement of these by readjustment of the point of view, combined with practice in the acts required to implant it firmly, along with pleasant emotional tone, among the habits of the individual. He indicates this difference in the application of therapy to the hysteric and psychasthenic, in that the latter wishes and seeks for counsel, support and direction, while the hysteric dislikes it at first, to become later only too willing a servant.

72. **Cancer.**—Dickinson reports the following facts in a paper read five years ago, but not previously published: About two and one-half miles east of Marion is a millpond of many years' standing, and around and near about are eight houses. About twenty-five years ago the patient in Case 1 died of cancer, his home being near the head of this pond. Not long afterward Patient No. 2 died of cancer of the breast. A few years later Patient No. 3 died of cancer of the lip and face. Some years later Patient No. 4 died of intercurrent disease, but had cancer of the breast well advanced. Patient No. 5 soon after died of cancer of the lip and face. Patient No. 6 is now confined to bed and if death does not come from some other cause must soon die of cancer of the breast. These people lived close to and around this mill pond on the Middle Fork of the Holston river, and all within a few hundred yards of each other. A few years ago iron ore was mined above them, the water being made muddy, and the people living in these houses all joined in getting an injunction to stop muddying the river, because it made their springs muddy. So it is fair to assume that the water used by them had some connection with the water in the pond and river. In addition to the above six cases, there have been three other deaths of people having cancer not far from this pond, and certainly two of the three frequented the mill at this pond for years and probably used this water. There are said to be now three other people with suspicious sores living in this vicinity, but the nature of these he can not affirm. He has since learned

of the death from cancer of the breast of another woman who lived for some time in one of the houses *near the pond;* also, of the three suspicious cases mentioned one patient has since died of cancer and another is well advanced in the disease. The author concludes: "However much this paper may point to the infectious nature of cancer, and away from heredity as a cause, it will be a failure if it does not suggest the importance of *general* practitioners collecting and publishing such clinical facts as may come under their observation, that they may serve as a basis and guide to laboratory workers; for these workers must explain in their theories the clinical facts of disease, before their conclusions can be adopted by our profession."

87 The Tonsillar Ring and the Paranasal Sinuses as Portals of Entry of Infectious Diseases S Rosenheim, Baltimore

82. Placental Syphilis.—Pauli reports the results of a study at Johns Hopkins in which 825 placentæ were examined, 25 being diagnosed as syphilitic. Autopsies were held on 16 out of 25 infants, in 14 of which an anatomic diagnosis of congenital syphilis was made The conclusions to be drawn from this study of the subject are:

1 The *Spirochæta pallida* is rarely found in syphilitic placentæ, and then only after long and tedious search

2 The anatomic changes observed in the placentæ, are the result of toxins produced by the *Spirochæta pallida* in the fetal organs, and not the immediate effect of the organisms on the villi themselves

3 The placenta is not the nidus of infection The fact that the *Spirochæta pallida* is never found in the maternal portion of the placenta, but only in the blood vessels and stroma of the fetal villi, would suggest that the placenta offers greater resistance to the invasion of the organisms, which is probably due to the steady flow of antibodies or immune substances from the mother through the maternal circulation

85. Diseases of the Blood and Sarcoma.—On a study of three cases, Bushnell arrives at the following conclusions:

1 These cases afford evidence that the glandular enlargements and visceral deposits of leukemia are closely allied to lymphosarcoma and that pseudoleukemia and lymphadenoma possess the characters of malignant growths

2 In leukemia the lymphocytes may be regarded as elements of malignant character

3 In sarcomatosis, and sarcoma of the lymph glands, changes may occur in the leucocytes (in the presence of transitional cells)

4 No absolute distinction can be drawn between leukemia and sarcoma

92 Puerperal Infection J O Gurney, Belzona

93 The Gall Bladder; Its Diseases and Treatment H M Folkes Biloxi

94 Nephritic Colic Synonyms: Renal Colic, Kidney Colic S L Knight, Hattiesburg

91. Senile Cataract.—Bell reports two cases which indicate very strongly the importance in senile cataract of possessing oneself, if posible, of the records of previous ophthalmoscopic examination. In the one case such a record would have added satisfaction and saved anxiety to the operator had he been able to be assured that the eye was healthy except for the opaque lens. In the other case the existence of previous records prevented a useless operation and the consequent depressing effect on the patient, and warns the surgeon that there is only one chance for securing vision, so that he may take certain precautions insuring more safety than he would were both eyes operable. The cases also show that glasses should not be fitted by any one unable to make and interpret an ophthalmoscopic examination unless normal vision, 20/20, is present in each eye separately with or without proper correcting lenses. In each case many different reading glasses had been fitted previously to the time a specialist was consulted In one case, fortunately, a record was obtained while still possible, but in the other case no examination had been made, leaving the examiner in much doubt and uncertainty as to just what condition was present behind the opaque lens The cases also point to the desirability of the general practitioners having the ability to use the ophthalmoscope in just such cases, as they are frequently consulted long before the patient goes to a specialist.

96 The Parathyroid Glands W Kirk, Troy, N Y

97 The Guest, or Personal Experience of a Patient in a Hospital for the Insane, told by Herself (Concluded)

95. The Parathyroids.—Kirk says that the total removal of the parathyroids is followed by acute symptoms, tetany, and death, in many animals. In man their complete removal ushers in a set of nervous symptoms of a serious importance In removal of the thyroid it is often difficult to isolate the little bodies, even in careful dissection, in a field limited in size and partially obscured by hemorrhage and staining of the tissues in the operative field. Hence it is easily assumed that they may be sacrificed in spite of the most careful precautions taken to ensure their safety. There may be a secondary or accessory blood supply to these small bodies—which would explain the failure of tetany to develop in certain cases of bilateral thyroidectomy.

1. **Massive Collapse of Lung.**—After discussing the mechanism of respiration, Pasteur points out that the expanding force of the diaphragm is exerted mainly on the portion of the lungs lying below the great fissures—that is, on the lower lobes—and a consideration of the cases in which the diaphragm has become paralyzed shows clearly what happens to the lungs when this expanding force is in abeyance. Respiratory paralysis is a comparatively frequent complication of diphtheria, and when the muscles of respiration are involved in this disease it is rare for the diaphragm to escape. He discusses a series of autopsy findings in such cases. There is nothing distinctive in the physical signs themselves, and it is often only by considering a case in all its bearings that a diagnosis can be made. The signs of the paralysis of the diaphragm are well known. Pasteur refers to one symptom which does not appear to have attracted notice. Exaggerated action of the lower ribs occurs, in his experience, in the majority of cases. and is one of the early indications of diaphragmatic failure. It is generally most obvious when the paralysis is well marked, and invariably disappears when function is restored. He discusses the probable causes of this phenomenon. The mechanism of massive collapse differs materially from that of patchy or lobular collapse. Massive collapse is essentially an active process, lobular collapse a passive one, for the former is brought about by the active exercise of the elastic property of the lung, while the latter is generally believed to be caused by a passive removal of the air from portions of lung which have been cut off by bronchial occlusion from communication with the external air. He concludes that if it has not been actually ignored, the importance of massive collapse has been underrated, while its clinical significance has been for the most part overlooked. Active collapse of the lung is generally caused by paralysis of the muscles which are the direct distenders of the lungs—the diaphragm and the intercostals—but there are strong grounds for believing that reflex inhibition of diaphragmatic movement may lead to the same result, and that this observation may throw some light on the nature of the postoperative lung complications.

2. **Angioneurotic Edema.**—Whiting describes three cases and gives a clinical picture of angioneurotic edema. He notes its markedly hereditary tendency and points to it as a familial cause of sudden death. In Great Britain and Europe, generally, males appear to be more frequently attacked than females, the reverse of the condition obtaining in America. The symptom-complex consists of more or less sharply localized edematous swellings, affecting the skin and subcutaneous tissues, the mucous membrane and submucous tissues, and possibly other structures. A frequent manifestation is the occurrence of periodical attacks of severe intestinal colic, with sometimes nausea and vomiting. The attacks have a cyclical tendency. The condition is allied with Raynaud's disease, intermittent hydrops of the joint, probably with erythromelalgia and acroparesthesia. In several of these diseases, edemas have shown themselves. It may be confused with atypical cases of urticaria. The prognosis as regards life is favorable, except in the throat and in the skin near the mouth, whence it might pass by extension to the throat. Not much can be expected from treatment in the absence of a definite pathology. Among drugs mentioned are iron, arsenic and strychnin when general indications call for them. Great improvement has been noted under quinin; nerve sedatives have not proved satisfactory, and nitrites have been of doubtful value. Nitroglycerin has proved useful. Whiting has seen clear benefit from dry thyroid substance. In throat attacks, dram doses of tincture of perchlorid of iron, repeated if necessary every twenty minutes, have given relief. Sucking butter proved of service in one case. In dangerous attacks intubation or tracheotomy is indicated. Patients subject to or threatened with attacks of edema of the glottis should constantly wear an actual or potential tracheotomy tube.

13 Postanesthetic Acetonuria, with Delayed Excretion of Acetone, After Childbirth. N. C. Forsyth.

9. **Chromocystoscopy.**—Brook discusses as a means of renal diagnosis the introduction into the blood current of pigments which are excreted by the kidneys and the observation by means of the cystoscope of their elimination by the ureters. It is simpler and more quickly conducted than either method of collecting the urine from the two ureters for examination, and is free from the objections and fallacies from which these suffer. The use of the separator, moreover, is not satisfactory without a cystoscopic examination. Chromocystoscopy is applicable in enlarged prostate and many other conditions in which other methods can not be practiced. The author describes cases in which by means of chromocystoscopy such questions as the following could be solved as preliminary to operative measures: In a case of a man formerly the subject of vesical calculus, there was tenderness but no pain in the left loin. The urine was acid, but showed no pus or albumin. Phthisical symptoms appeared. A skiagraph showed two ill-defined shadows, one at either pole of the left kidney. The following questions required answering before deciding on treatment: 1. What was the condition of the right kidney? 2. How far was the left kidney disabled? 3. How far was the general condition dependent on the lung mischief, and how far on the disease of kidney? Chromocystoscopy showed heavy blue-black jets issuing from the right ureteral orifice and none at all from the left. From the examination and the above-mentioned symptoms and history, it was possible to supply the following answers: 1. The right kidney was in good working order. 2. The left kidney was physiologically destroyed and the pelvis blocked, so that no pus found its way into the bladder. 3. In spite of the existence of the lung disease, that of the kidney, namely, suppuration behind a blocked ureter, was quite sufficient alone to account for the general condition. Brook thinks that the method is deserving of more extended recognition and general application than it receives at present, and urges that it should be included in the routine course of examination of all renal cases before operation, and of all abdominal tumors when there is the smallest possibility of their being of renal origin.

12. **Cancer.**—In a summary of 1,700 cases of cancer occurring in Travancore, India. Bentall arrives at the conclusion that the frequency of cancer of the buccal cavity and its absence in the rest of the alimentary canal is suggestive of a local cause for the former and of absence of digestive causes in the latter. He suggests that in the Hindoo the inveterate

habit of betel chewing from childhood possibly indicates a cause, due either to mechanical irritation or to a medium suitable for the growth of a possible cancer germ.

21. **Mental Diseases.**—From an investigation at Callan Park Hospital for the Insane, Sydney, Davidson finds that the three main causes, numerically, were, (a) intemperance in drink, (b) heredity, and (c) domestic trouble. In this last doubtless the first two played a large part. Other causes were venereal diseases, fevers, epilepsy, phthisis, and the human epochal conditions—puberty, etc. He discusses each of the three major causes in detail. He agrees with Thomson that inheritance is usually a general, not a specific predisposition, though there are some instances of apparently precise and specific inheritance, and that there seems little warrant for believing in the transmission of acquired nervous disease. He points out that there seems to be an affinity or attraction between families with a tendency to nervous diseases. He quotes Dr. Charles Williams' five rules for the guidance of physicians when asked for an opinion as to the advisability of marriage, which may be summarized as follows: 1, No person should ever marry another of weak intellect, or who has been certified as insane; 2, two persons should never marry with a family history of insanity on both sides; 3, even when the family history of insanity is on one side only, it is exceedingly unwise to marry; 4, first cousins should seldom if ever marry; 5, no one should ever marry a sufferer from chronic epilepsy, even of the mild type. Beyond giving advice, however, it is difficult to see what can be done, unless statesmen are bold enough to intervene, and declare such marriages illegal and the children illegitimate. Davidson draws a striking picture of the rapid maturity and decline of certain young highly strung nervous children, which results in premature decay, possibly even imbecility, and urges that the thorough examination of school children might check some of these conditions. He considers it desirable that chronic alcoholics in all classes of society should be placed under control, whether they desire it or not. Again, syphilis, owing to its destructive effects on the brain, must be recognized as one of the chief causes of insanity. Like alcohol, it does not finish its ravages on the person affected, but is a hereditary disease unto the third generation and probably of a much more virulent type. He champions its causative relation to general paralysis and explains the fact of districts existing in which syphilis is very prevalent, while general paralysis is exceedingly rare, by the absence in these districts of the exciting cause. The two are associated more in large business centers, seaports, and places generally where life is more or less energetic, and are less associated in quiet, peaceful and uneventful rural districts, and among people of an easy-going character. He urges that syphilis should be a notifiable disease and that public establishments for its treatment should exist and be made widely known. In regard to the treatment of early cases of mental disease, he urges a legal clause, such as exists in Scotland and England, which allows persons to become voluntary patients, with the right of leaving with so many days' notice of their wish. An examination of the results of this method of Glasgow shows: 1, That the recovery rate of voluntary patients is greater than that of certified patients; 2, that the duration of treatment is shorter; and, 3, that in only a few instances does certification become necessary. He urges that patients should be carefully classified and different hospitals be established for: 1, The criminal insane; 2, the epileptic insane; 3, the senile insane; 4, imbeciles and idiots, with school education or those slightly impaired mentally, who might earn a livelihood; and 5, for chronic patients who have become "hewers of wood and drawers of water," in the biblical sense, and for whom an agricultural colony should be established. Such classes of patients should not be hopelessly muddled together.

22. **Arneth's Classification of Leucocytes and Pulmonary Tuberculosis.**—Griffiths considers that Arneth's work has not received the attention it deserves. He summarizes it and describes the technic. In regard to the stain, he points out that Arneth is very emphatic that Ehrlich's triacid stain should be used, but Griffiths prefers Jenner's stain, a modification of Romanowski's eosin and methylene blue stain, with which Arneth does not appear to be acquainted. If Ehrlich's stain is used, one must be careful to secure Ehrlich's triacid *farbung* and not the *trifarblösung*, which is a different preparation and not at all suited for the work. While the labor of Arneth's method is great, it is not so great as that of an opsonic estimation, and has over the latter two great advantages: Arneth's method is direct and absolute; its object is to determine one aspect of the state of the patient's blood, and this object it achieves. The opsonic method is indirect and relative; by it we determine not the absolute opsonic power of the blood, but the ratio of the opsonic powers of bloods of two persons, or of the blood of one person (the patient) and of the mixed bloods of a number of persons. Moreover, the opsonic index of a patient's blood may be doubled or halved in a couple of hours as the result of food, exercise or emotion, and so one can never know what it is, but only what it was some hours previously, and by the time the observation is completed it may be something very different.

23. **Movable Kidney.**—MacLaurin says that the operation which he now does for movable kidney is simply the formation of a shelf beneath the viscus. An incision is made from the tip of the twelfth rib downward and forward, which is deepened by muscle-splitting; the peritoneum is pushed forward; the canary-yellow fatty capsule of the kidney is stripped off and removed from its attachment around the hilum; the kidney is brought to the surface, split up the middle and examined; if found normal it is sewed up again, the peritoneum and Zuckerkandl's fascia are sewed to the fascia covering the quadratus lumborum with interrupted sutures of chromic gut, and the wound is closed.

40 Treatment of Congenital Dislocation of the Hip. F. Barnes.

37. **Causation of Neuroses.**—Jordan asks the following questions: 1. Is the nervous system of any child so congenitally defective that in spite of proper treatment and education from the first the child must grow up neurotic? The answer he believes to be yes, though, apart from actual imbeciles, of very few. 2. Is the nervous system of any child so congenitally perfect that no illness or error of training can render it neurotic? The answer to this he believes to be no. Both answers emphasize the importance of the postnatal causes of neuroses, of which he particularly discusses the habitual constipation of infancy and childhood and septic tonsillitis of the follicular or lacunar type.

39. **Feeble-Minded Children.**—It has appeared to Potts for some years that there is a close connection between the type of a feeble-minded child and its origin. This is not unlikely, for the offspring of tuberculous and syphilitic stocks are readily recognized, and there is no reason why the different types of feeble-mindedness should not have a definite heredity. The type greatly influences the prognosis. He considers in detail the Mongolian type, holding that these are essentially unfinished children, born when the procreative powers are at a low ebb; the simple congenital type, which, in his experience, is pathognomonic of an insane or feeble-minded ancestor; the neurotic type, which he has little doubt is pathognomonic of an alcoholic heredity; and the moral defective, in which the guide to classification is the social conduct. This type exists and its recognition is important. On the other hand, the author's observations in prisons have convinced him that only very few of those found there can plead this abnormality as a justification.

49 Simple Technic for Dosage of Gases in Coal Mines. (Dosage exact du formène (grisou) et de l'oxyde de carbone dans les mines de houille par des procédés simplifiés.) N. Gréhant.

48. **Intradermal Tuberculin Reaction.**—Mantoux introduces the needle almost parallel to the skin, aiming to reach the under surface of the derma, and then injects one drop of a 1 to 5,000 solution of Pasteur Institute tuberculin. The local reaction is extremely characteristic and the technic can be made uniform more exactly than with certain other methods. He reports his findings with the test on 326 adults and 47 children, and the results of much experimental research. The technic is free from the dangers of the ocular reaction and is much more reliable, he states, than the ordinary cutaneous test. The specificity and sensitiveness have been proved in the clinic by comparison with autopsy findings and with the results of other tests and by the findings of the test on 70 cattle, 23 swine, 4 goats and 6 lambs, a total of 103 animals. Positive findings indicate the presence of a tuberculous focus somewhere and negative findings indicate with approximate certainty freedom from tuberculosis except in the moribund and in persons with measles or smallpox or recently vaccinated. The intradermal technic may also prove useful as a guide in tuberculin treatment, showing the sensitiveness of the patient.

50. **Diagnosis and Treatment by Change of Position of Dilatation of Stomach from Atony.**—As the patient stands, the atonic sagging stomach forms a low bag, the outlet of which, at the pylorus, is considerably higher than the level of the fluid contents in the stomach. If the patient then lies down on the right side, the fluid in the stomach flows down toward the pylorus, and if this opening is unobstructed the stomach soon empties itself. The splashing sound after an hour of erect position and its absence after the patient has been lying on his right side for an hour, help to differentiate the condition. The stomach may be able to evacuate its contents normally when they do not surpass a pint in amount, while a quart exhausts it completely. The stomach may also become transiently atonic during a period of worry or fatigue, regaining its normal tonicity afterward. These transient gastroplegias can be influenced frequently by appropriate therapeutic measures. Persons subject to them should refrain from loading the stomach so long as they have to be up and about, and should select food that will be promptly expelled, such as clear soups, with tapioca and beaten eggs, milk skimmed and sweetened with 1 gm. of sodium citrate to the quart, syrups and egg water. The more substantial meals should be digested reclining, in order to suppress the action of vertical pressure on the stomach, and to keep the pylorus at the lowest slope of the organ. The patient must recline on his right side, with the pelvis raised, lying down immediately after the evening dinner. If the raising of the pelvis is uncomfortable, it can be limited to an hour or so, commencing two hours after the meal. If other organs are involved in the ptosis, it is best to keep the patient in bed for a time to cure the reflex disturbances. Graduated motor and secretory gymnastics of the stomach by ingestion of increasing amounts of food—merely avoiding food with much waste—may have a very favorable influence. Recent research has shown that restriction of the diet has a tendency to increase the weakness of the stomach walls.

56. **Mental Disturbances in Ovarian Syndrome.**—Lavastine discusses first the psychology at puberty. The mental confusion, melancholia or excitement, sometimes observed in girls and accompanied by other symptoms of ovarian insufficiency, such as headache and backache, asthenia and insomnia, is frequently cured by treatment with ovarian extract, thus testifying to the influence on the mental condition of the internal secretion of the ovary. The psychoses dependent on menstru-

ation are evidently of a toxic nature, as is demonstrated by their appearance at the approach and at the conclusion of the menses, by the toxicity of the menstrual flow and the increased toxicity of the blood at the approach of the menstrual period, and, further, by the benefit from ovarian treatment in the menstrual psychoses and also in others with exacerbations corresponding with dysmenorrheic periods. The thyroid may also play some part in the toxic syndrome; E Thomas has reported a case of menstrual psychosis with periodically recurring goiter, exophthalmos and ophthalmia. The psychic disturbances of pregnancy may be simple elementary troubles or actual psychoses; in some of the latter the pregnancy is merely an occasional cause; in others, of toxic nature, the pregnancy is evidently directly responsible for the psychosis. The mechanism varies in different cases, in some there is evidently ovarian insufficiency; others with thyroid or parathyroid symptoms and enlargement of the thyroid, along with eclampsia and tetany, may be the result of disturbances in these glands. Postpartum psychoses are generally of toxic origin and streptococcus or anaerobic infection is generally responsible, a few cases being attributable to autointoxication from insufficiency of liver and kidney functioning or thyroid disturbances. The ovaries may occasionally be incriminated along with the sudden loss of the placenta with its internal secretion and, possibly, disturbance from an internal secretion on the part of the mammary glands A tendency to lactosuria and compensating hypertrophy of the breasts seems to save certain women with insufficient thyroid functioning from myxedema; these cases sustain the assumption of an internal secretion. On the other hand, the ovaries are almost solely responsible for the psychic disturbances accompanying castration. The existing nerve balance in the women generally determines the severity of such disturbances. In women without appreciable nervous stigmata the psychic disturbances are generally elementary and yield readily to ovarian treatment, but in women predisposed by inherited or acquired taint, the psychoses are usually of the degenerate type, with the castration merely as an occasional cause, or else of the mental confusion type, toxic psychoses, of varying intensity. They can all be improved and some cured by treatment with ovarian extract. There are four types of acquired ovarian insufficiency: the nervous, congestive, nutritive and adipose. Congenital insufficiency is generally revealed by a suggestion of infantilism Hyperfunctioning of the ovaries may be responsible for erethism, local pains, neuralgia, congestions and hemorrhages, but the five groups of symptoms of insufficiency include beside the classic hot flashes" and tendency to congestions and hemorrhages, especially in the lungs, a tendency to obesity, modification in the genital sense and neurasthenia, with constant slight headache, buzzing in the ears, vertigo, frequent insomnia, nightmare, facial neuralgia, attacks of spasmodic suffocation, depression, palpitations, dyspeptic disturbances and modification of the mental state. The conditions in the menopause are essentially of the same nature as at puberty, with a tendency to sadness on account of encroaching age. The psychic disturbances characteristic of ovarian insufficiency are weakening of the memory, changes in character, irritability, even a tendency to hypochondria, ideas of suicide and general loss of energy with physical depression and nervousness—never actual psychoses.

57 **Intestinal Cancer and Foreign Body.**—Okinczyc and Combier report a case of a small cancer at the sigmoid flexure in which a prune stone was found imbedded. A foreign body arriving at a cancerous stenosis is liable to close the passage completely, the sudden severe occlusion from this cause being sometimes the first sign of the presence of the cancer. A number of such cases are on record, and the authors summarize some of them. The most remarkable is certainly Cruveilhier's case in which a woman presented long rebellious diarrhea, no occlusion, and at autopsy a cancerous stricture was found in the transverse colon and above it 617 cherry stones.

58 **Anuria with Cancer of Rectum.**—Papin reports a case personally observed and gives the details of four others that have been published in which anuria was a prominent complication of cancer of the rectum In the personal case described the anuria was the *first sign of trouble*. It persisted for five days and was accompanied by rebellious diarrhea and later by vomiting. The bladder and prostate were examined through the rectum, but the cancer involving the rectum and sigmoid flexure was not discovered. As a kidney stone was surmised, nephrotomy was done Papin urges examination of the ureters at autopsy in cases of rectal cancer, and remarks that uremia may be responsible for some of the symptoms in the terminal phase of these cancers. Anuria may result from direct compression of the ureters or from reflex action.

59. **Remote Results of Hysterectomy for Uterine Cancer.**—Jayle discusses 28 cases from his experience and states that the 5 patients with localized cancer of the body of the uterus have been cured for intervals of from 2 to 6 years, with the exception of one who died after the sixth year from unknown cause. Six with cancer of the cervix, without involvement of the broad ligaments, are in good health from one and a half to seven and a half years later. In 17 cases of cancer that had spread beyond the uterus, 5 of the women did not survive the operation and 9 succumbed within a year, while 3 are in good health from five to eight years since, and 3 have been lost trace of.

60. **Accidental Staphylococcus Infection of Genital Organs**—Boshouwers relates a case of this kind in which he was able to cultivate the *Staphylococcus pyogenes albus* from a suddenly appearing infectious process in the vagina of a young woman The same micro organism could be cultivated from the well water used for bathing, and two little girls in the family also suffered from a similar vulvovaginitis

61. **Inguinal Hernia of the Uterus.**—Cranwell recently found in a strangulated hernia an atrophied uterus with the adnexa on that side He reviews a number of similar cases from the literature, adding that five cases are on record in which inguinal hernia in males contained a rudimentary uterus or adnexa. In the presence of an irreducible inguinal hernia whose contents are hard and the shape suggests that of the uterus, it is important to palpate through the vagina to determine whether the uterus is actually involved. Hernia of the uterus is frequently accompanied by malformation of the internal genital organs If the contents of the hernia can not be reduced, it is best to remove the organ. Cesarean section was done in 5 cases in which the woman was pregnant, 4 of the mothers died and 1 of the children. In 2 other cases premature delivery was induced, with good results He gives the details of the 44 cases on record besides his own

63 **Subphrenic Abscess.**—In this third memoir Catz and Kendirdjy give the details of hundreds of cases, classifying and discussing the abscesses according to their location and etiology. The article is illustrated and presents a comprehensive study of abscesses of appendicular, gastric, duodenal, pancreatic, biliary, splenic, traumatic, tuberculous and thoracic origin, some of these types requiring much research on the part of the authors.

74 *Diagnostic Significance of Antitryptic Power of Serum. (Le pouvoir antitryptique du sérum a-t-il une valeur diagnostique?) L. Ambard.

73. **Immediate Versus Deferred Operation for Ruptured Tubal Pregnancy.**—The conclusions drawn by de Bovis from the evidence at hand to date are that it is not necessary to wait for the subsidence of shock before operating for ruptured ectopic gestation. The cases in which the hemorrhage becomes spontaneously arrested and those in which the forces are at such a low ebb that the slightest traumatism is fatal, are extremely rare. He advises early but not precipitate intervention except when the environment or other conditions contraindicate it, but warns that this does not mean that any physician at any time should feel justified in operating in case of ectopic pregnancy. The hemorrhage is usually slow and gradual, and there are thus a few hours at the physician's disposal to combat it. This is no reason for wasting time, for minutes count in hemorrhage, but it is a reason for not assuming too soon that the situation is desperate.

74. **Diagnostic Significance of Antitryptic Power of the Serum.**—Ambard discusses the property sometimes possessed by the serum to inhibit the action of trypsin and thus check digestion by the pancreatic juice. This antitryptic power was found especially pronounced in cases of cancer, and it was assumed for a time that it was pathognomonic of cancer, but later research has demonstrated this antitryptic power in a number of diseases and even in apparently healthy persons. He states that the proportion of pancreatic secretion found in the stools after a purge, by dosage of the fecal amylase, was nearly twice the normal proportion in two cancer patients. Other observers also have recently pointed out that the antitryptic power of the serum is much enhanced by injection of trypsin in animals and ingestion of pancreatic extract in man. Ambard concludes that the increased antitryptic power in all conditions is a sign of hyperfunctioning on the part of the pancreas. Lack of pepsin and a compensating hypersecretion on the part of the pancreas form a common link between cancer cachexia, nephritis and other conditions in which the antitryptic power of the serum is increased. The latter is thus an indication of excessive functioning on the part of the pancreas and thus proves a means of obtaining an insight into the workings of that organ.

76. **Oil in Treatment of Stomach Affections.**—Rütimeyer reviews *the history of systematic treatment* of stomach affections with oil, and describes his own experience with 100 cases. In some cases of hypersecretion and hyperacidity, with or without neurasthenia, the secretion was reduced when 30 gm. butter or 100 gm. warmed oil was taken fasting in the morning. In another case of threatening postoperative spasm of the pylorus, with extreme dilatation of the stomach, 100 gm. of oil poured into the stomach each morning, with lavage of the stomach twice a day promptly cured the spasm. In one case a merchant of 41 presented signs of chronic ulcer and spasm of the pylorus with excessive secretion and intense pains; only partial and transient benefit was obtained during two years of various measures. The old troubles returned at every excessive effort or excitement or dietetic error, and finally an operation was proposed. A systematic course of oil was instituted as a last resort, with brilliant success. The patient rinsed out his stomach every morning and then took 100 gm. of oil, and in two weeks the pains and spasms had vanished. The man gained rapidly in weight and was soon able to eat any ordinary food. During the five years since he still occasionally takes a little oil after some gross dietetic error, and it promptly relieves any slight disturbance. The most striking benefit of the oil treatment is in its influence on the subjective disturbances. The oil banishes the pain and restores the earning capacity, even although the objective findings may occasionally persist unmodified.

78. **Prognosis and Treatment of Vasomotor-Trophic Neuroses.**—Cassirer discusses Raynaud's disease, erythromelalgia, sclerodermia, sclerodactylia, and Quincke's transient angioneurotic edema. All these affections are functional nervous disturbances, and all have a similar course with a tendency to recur with latent intervals. The prognosis is favorable in so far as there is seldom transition into an organic nerve or other trouble. At the same time the affection may recur at intervals for years and decades. There is also a close connection between these and other functional neuroses, neurasthenia and hysteria. The prognosis must therefore be guarded, as even if the vasomotor disturbance subside, complete restoration is rare. Treatment should aim first to avoid all causes that may induce the disturbance, cold water, handling cold damp articles and overexertion. In several cases of Raynaud's disease, Cassirer obtained good results with local hyperemia, winding the upper arm with a flannel bandage to induce venous stasis. This was done daily for half an hour during several weeks. This measure failed, however, in very severe cases. He is inclined to accept some connection between these neuroses and the arthritic diathesis. In the angioneurotic edema, regulation of the diet and of the bowels has often aided in the cure. Quinin and atropin may also prove useful, as well as arsenic. Especially disagreeable are the neurotic gastric symptoms, resembling the gastric crises of tabes, and sometimes so severe as to require morphin.

80. **Polycythemia and Blood Pressure.**—Möller concludes from his own experience and study of the literature that there is no direct connection between high blood pressure and the *number of the blood corpuscles. Examination of 35* patients with a blood pressure of 180 mm. mercury and above, showed that only two of the patients had an unusually large proportion of red corpuscles.

81. **Family Tree for Studies of Heredity.**—Crzellitzer gives some examples of a method of making out a family tree which is simple and very instructive. The male members of the family are represented by small squares and the females by circles, cross bars in the squares or circles showing the members of the family affected with the special feature being studied. Name, date, age, etc., can be written in each square or circle.

82. **Comparative Pathology of Tuberculosis.**—Lubarsch has been examining *the calcified foci* in human cadavers and in animals. He found tubercle bacilli still infectious in certain isolated, totally calcified foci in men, cattle and pigs, but this was very rare in human beings, while it was almost constant in cattle and in swine. He accepts this as evidence that the calcification process has a more curative tendency in man than in animals.

83. **The Serum Test of Syphilis.**—In the research described, special attention was paid to whether or not positive findings could be obtained with persons who were apparently entirely free from syphilis. This was the case in 17 out of 107. In several of these cases, however, the complement binding was transient. Blood from cattle, instead of sheep blood, permits a reaction exclusively specific for syphilis to be differentiated from a non-specific reaction which may be observed in various other affections.

84. **The Biologic Principle of Radiotherapy of Cancer.**—Diesing regards the pigment in the skin which forms under the action of sunlight as the preliminary stage of hematin, and thus of great importance for the metabolism. The ultraviolet rays stimulate these pigment-producing cells to functioning, and excessive stimulation is liable to lead to malignant proliferation. Light can thus induce the production of cancer, he says, but it can also cure cancer when applied in the form of Roentgen rays. He advises scarifying the skin over the cancer, opening up as many entering points for the Roentgen rays as possible. After removal of a cancer the part should be thoroughly treated with the Roentgen rays to destroy as many as possible of these pigment-producing cells below the site of the cancer. He is certain that the proportion of permanent cures will grow much larger when this is done as a routine measure.

86. **Treatment of Puerperal Infection.**—Henkel concludes his long article with the statement that serum treatment is unreliable in severe cases of puerperal sepsis and pyemia. They require unconditionally surgical measures; only by this means is there a chance to combat the consequences of severe puerperal infection. Early extirpation of the uterus is required for puerperal sepsis, and ligation of the thrombosed veins, at the right time, in puerperal pyemia. The Trendelenburg and Bumm technics are the only ones for the latter, and he prefers Bumm's transperitoneal method on account of its simplicity and the ample oversight it allows. The ovarian vessels are ligated and excised, the stumps cauterized with the actual cautery, the iliac vessels are ligated and the sheets of the peritoneum are sutured. The crucial point is the decision as to the proper moment for operating. This is when the thrombosed vein can be distinctly palpated, eventually under general anesthesia. No operation should be attempted, he says, if an exudate has formed around the thrombosed vein, as in this case streptococci are already present in the infiltration and a transperitoneal operation is too dangerous. In dubious cases the general anesthesia is of great importance, as it allows the normal tubes and ovaries to be palpated and thus to be excluded from the clinical picture. Analysis of the unsuccessful cases on record shows that the operation came too late. It is important to seek for a middle iliac vein; one is sometimes found between the external and internal iliac veins. He reports an instructive case, another to add to the "too late" category. Intervention a little earlier might have saved the patient.

93 Complement-Binding Te [illegible] Meningitis. W. Schurmann.
94 Results of Experimental Research on Heredity. (Einige Ergebnisse der experimentellen Vererbungslehre.) E. Baur.

88. **Industrial Morphin Poisoning.**—Lewin's patient was a man of 64 who had worked for thirty-four years in a chemical factory, for the last twenty-five years being engaged in the making of apomorphin. Last August he was employed in the morphin room, and had occasion to wash some cloths which had been used for filtering morphin. His hands itched at once and a severe dermatitis developed on the arms, resisting all treatment for two years; he died before the close of the third year. Lewin testified that the case was a classical example of an industrial poisoning accident and the family was awarded an indemnity.

89. **Pernicious Anemia.**—Continuing this symposium on pernicious anemia, von Noorden says that about 40 or 50 per cent. of the cases terminate in recovery, and that even the malignant cases have remarkable fluctuations. He has found arsenious acid the most reliable drug, and remarks that the patients need warmth, sunshine and fresh air. Mountain climate has done harm rather than good in his experience. Strümpell ascribes great importance to the differentiation of pernicious anemia from latent cancer of the digestive tract, and thinks that this is possible by determination of megalocytosis and the higher color index. Both these are processes of compensation which are nearly constant with pernicious anemia, while they are exceptional with secondary carcinomatous anemia. The discovery of megaloblasts speaks for primary essential anemia, as also a pronounced reduction in the numbers of white corpuscles, especially of the myeloid elements, while the lymphocytes are relatively increased. With cancer there is generally leucocytosis. Small doses of phosphorus have sometimes proved beneficial in his experience, and he adds that saline transfusion or Ziemssen's injections of blood deserve further trial, as they may have a stimulating action on the bone marrow.

90. **Peculiar Reaction to Electric Energy in Hysteria.**—Kahane is in charge of the Institute for Physical Therapeutics at Vienna, and has been studying for years the therapeutic action of high-frequency currents. As a rule, he says, their local application has a vasoconstricting, secretion-checking action, while pain and itching are reduced. Their general application has a soothing effect in most cases, and this sedative action has proved very beneficial in neurasthenia. On the other hand, in hysteria the high-frequency currents invariably produced the reverse of their customary effect. In every case the condition was immediately aggravated and an attack brought on in the monosymptomatic cases. After the general d'Arsonvalization the hysteric patients complained of disagreeable sensations in their limbs, and it seemed as if the balance in the nervous system had been upset. This peculiar and unprecedented reaction to the high-frequency currents suggests the possibility that the condition known as hysteria may result from modification in the nervous system affecting its reaction to certain forms of electric energy.

91. **Zinc Gelatin Dressing for Leg Ulcers, Varices and Joint Affections.**—Hecker has found Unna's zinc gelatin dressings useful in treatment of these troubles, as it counteracts the tendency to stagnation in the circulation, while it gives an unfailing support and does not interfere with the patient's business. Other advantages are that it is inexpensive and clean, and can be applied by any practitioner and does not require renewing for weeks. Unna's formula has never been improved on, he says:

R

Zinci oxidatis.				
Gelatini	āā	10	or	ʒiiss
Glycerini.				
Aquæ destillate	āā	40		ʒx
Ichthyolis		2	5	gr. xl

The leg is scrubbed and shaved, then cleansed with ether or benzin and the gelatin preparation, softened by warming, is spread on the entire leg except at the site of the ulcer. A strip of cotton is then laid below the knee and above the toes and two starched roller bandages about ten yards long and four inches wide are wound around the leg from the toes up, leaving the toes exposed for control of the circulation in the limb. The secret of success is to have the bandage wound so as to exert a strong, even pressure. This "skin splint" is cut off with plaster-shears when renewal is deemed necessary, once in three weeks at first, but later not for four or six weeks. If the stiff bandage binds at any point, all that is necessary is to moisten this part with warm water and it will soften and adapt itself to the surface as desired. He has found that old rebellious ulcers begin to heal at once under this treatment, and that the scars are stronger and firmer than with any other technic. He has found these gelatin dressings useful also in cases of effusions in the joints and as an aid in various surgical procedures.

95. **Function of the Placenta.**—Bergell and Falk report research which demonstrates that the placenta is an organ participating in the metabolism, regulating the metabolism in the fetus

96 **Paratyphoid Bacilli.**—Mayer presents evidence to prove that paratyphoid bacilli retain their vitality in dried human stools for a year and a half if protected from sunlight. He ascribes to this long resisting power several endemics in his experience.

98 **Evil Consequences of the Ocular Tuberculin Reaction.**—Schrumpf describes two cases in which instillation of tuberculin in the eye of a drop of a 1 per cent. solution of "old" tuberculin induced inflammation, which was very long in healing and left permanent opacity of the cornea in one case. The patients were women of 65 and 81, and the parenchymatous keratitis induced resembled very much ordinary tuberculous inflammation of the cornea He cites further 23 authors who have published reports of disturbances in consequence of the tuberculin instillation, ranging from intense conjunctivitis to keratitis with or without involvement of the iris. In both of his cases the eyes were previously certainly sound Another disadvantage of the ocular reaction is that the eye process is liable to flare up again if a course of tuberculin treatment is instituted A positive reaction to the tuberculin instillation has also a depressing influence on the patients.

104. **Habitual Malignant Jaundice.**—Pfannenstiel applies this term to the cases in which several infants in turn in the same family develop malignant icterus soon after birth He has had a case of this kind in his own practice and learned of two more in his district, and has found a few on record. In his case a healthy young woman had four children, born in the course of four years, all apparently healthy and well developed, and yet the last three all died in a few days from malignant jaundice which developed soon after birth Large quantities of dissolved bile pigment were passed in the urine; the stools were colored with bile, but the infants presented peculiar meningitic symptoms which increased and subsided in waves, with opisthotonos and tonic spasms of the arms, and the various mucosæ showed a tendency to catarrhal discharges of a yellow tint The only difference noticed in the different children was the amount of resistance they were able to oppose to the affection, some lasting longer than the others before succumbing to the malignant affection The first born never displayed the tendency to jaundice and has always been healthy. The findings at the autopsy of each of the jaundiced children are described in detail, and the cases in the literature are reviewed and compared with them In some cases this habitual jaundice has been observed up to nine times in one family, but healthy children may grow up healthy between the jaundice children He does not believe that there is any essential difference between the mild form of this habitual jaundice and the so called "physiologic icterus" of the new-born. Syphilitic infection was not present in any of the cases to date, and other infections are scarcely probable When jaundice is observed in an infant energetic measures to eliminate the toxin are indicated at once. Diuresis should be stimulated by giving the child as much water or fennel tea as possible, with the meals or alternating with them. An alkaline water might prove useful. Subcutaneous infusion of saline solution, from 100 to 150 c c, should be given, repeated if necessary. Warm baths with cool douches are indicated to stimulate the circulation and the functioning of the skin. Small doses of calomel at the beginning may be useful, later cautiously rinsing out the intestines with chamomile tea, keeping the child warm and protected from bright light and noises as it is very sensitive and wakes readily. Breast feeding is imperative, not allowing much at a time to avoid stimulating the secretion of bile. Once in four hours is often enough if water is given copiously in the interim. Treatment otherwise must be symptomatic, combating the tendency to hemorrhage sometimes observed. In one of the children in his experience hemorrhage from the umbilical cord persisted unmodified until after an injection of gelatin. By application of treatment along these lines one of the children survived for three weeks, and if the affection had been a trifle less severe might possibly have recovered. He urges further research on the jaundice of the new-born on the part of obstetricians, pediatrists and pathologists.

105 **Pay for Trials of New Drugs.**—A previous summary of the action of the German Medical Press Association on this subject was given in The Journal, November 7, page 1613 The editor of the Munich weekly takes a more decided and extreme stand than the other members of the association, and here reiterates his contention that the principle should be upheld denouncing acceptance of remuneration from the manufacturers for trials of pharmaceutic preparations in the clinic By surrendering this principle, he says, the struggle against fake medical write-ups is rendered immeasurably more difficult

109. **Serum Diagnosis of Syphilis.**—Grosz and Volk report the results of the serum test in 178 cases, including 124 syphilitics The later history of the patients in connection with the findings confirm the extremely valuable and reliable information to be derived from the test when the findings are positive, but negative findings are inconclusive.

112 **Sensitizing Action of Animal Pigments and Its Physiologic Significance.**—Hausmann announces that bile has a powerful photodynamic action Red blood corpuscles mixed with bile and exposed to the sunlight rapidly disintegrate, while a similar solution kept in the dark remains unchanged. A concentration is used for the tests free from hemolytic action as long as it is not exposed to the sunlight Hematoporphyrin has a still more pronounced sensitizing action than bile alone. He is inclined to believe that these substances, like chlorophyl, exert their sensitizing action only at certain points and are otherwise inert, like the photographer's sensitizing substance, which is inert so long as he keeps it in its jar; it displays its specific power only when spread on the photographic plate. In studying the effect of light on the organism, the possibility of a sensitizing action from some of these substances must be borne in mind, he says. An insufficiency of the sensitizer or an excess may be one of the factors in certain skin affections; bacterial products may also have a sensitizing action. Possibly, he suggests, the action of mountain climate may have something to do with these sensitizing factors.

114 *Method of Sterilizing the Skin for Operations. (Neue Sterilisierungsmethode der Haut bei Operationen.) A. Grossich.
115 *Explanation of Postoperative Spastic Occlusion of Intestine. (Zur Erklärung des *postoperativen spastischen Darmverschlusses.)* F. Franke.
116 *Fatal Bismuth Poisoning. (Wismutvergiftung durch Injektionsbehandlung *nach* Beck.) *H.* Eggenberger.

114. **Improved Method for Sterilizing the Skin.**—Grossich applies a 10 or 12 per cent. tincture of iodin to the field of operation and to disinfect the skin around, without any preliminary scrubbing with water. His microscopic studies have shown that the tissues take up the iodin much more readily when they are dry, and that it penetrates deep into all the nooks and crevices, which does not occur with the usual preliminary scrubbing with soap and water. The water macerates the epidermal cells and they swell and plug the openings. He relates his experiences with this technic, especially in a large number of cases of open crushing wounds in laboring men. The parts are shaved, dry, and then painted with the tincture of iodin, and a sheet is then laid over the naked patient with a hole over the field of operation—the sheet fastened to the skin with a few small clamps and reaching to the floor all around. After the patient has been anesthetized, the field of operation is painted a second time with the tincture of iodin and the completed suture is swabbed anew with it. He has never witnessed any by-effects from this technic, not even when a third of the body was painted with the iodin. This technic he is convinced eliminates all danger of infection from the patient. He applies it only when the wound is still entirely free from signs of inflammation such as redness and swelling. If the tincture of iodin is applied after the parts have been recently scrubbed with soap and water, there is liable to be suppuration; *it is indispensable* that the tissues should be dry when the iodin is applied for this purpose.

115. **Postoperative Spastic Intestinal Occlusion.**—Franke ascribes postoperative ileus to a traumatic neurosis of the intestines, *and cites a number* of arguments to sustain this view, remarking that the trauma may be either mechanical or psychic. He has observed cases in which the postoperative ileus developed after fixation of a wandering spleen, the intestines not being involved in the operation at all. In one case, the occlusion occurred before *the operation had* been commenced, and subsided spontaneously later. He has also observed cases in which this *form of ileus was* undoubtedly the result of the action of belladonna or physostigmin, given to stimulate peristalsis, but possibly *in too large dosage*. The ileus subsided *completely in two* such cases in his recent experience when the drug was suspended.

116. **Bismuth Poisoning from Local Injection in a Fistula.**—Eggenberger injected 30 gm. (450 grains) of 50 per cent. bismuth vaselin into a spondylitic fistula in the abdomen of a boy of 7. He had applied *this treatment with good success* in several cases previously, following Beck's directions. The bismuth vaselin was left in the fistula and the boy grew puny after six weeks, with a stomatitis suggesting mercurial poisoning, and with ulcerations on the gums and lips. On the assumption of bismuth poisoning, the abscess was opened and evacuated, but the *symptoms progressed*, the syndrome resembling the picture of uremic toxic irritation of the cortex, and proving *fatal in a few days*. Autopsy revealed punctate hemorrhages in the stomach mucosa and an ulceration in the cecum, *with the mucosa and the brain cortex* hyperemic throughout.

117 *Cure of Dysmenorrhea and Amenorrhea Under Tuberculin Treatment According to K. Spengler. (Tuberkulose und Menstruation.) K. Eisenstein and J. Hollos.

117. **Relations Between Tuberculosis and Menstruation.**—Eisenstein and *Hollos* report experiences which seem to show that the ovarian system regulating menstruation reacts most sensitively and intensely to the influence of tuberculous toxins so that the great majority of tuberculous women suffer from irregularities in menstruation. They further assert that tuberculin treatment has a most remarkable influence on these menstrual irregularities and pains, promptly restoring conditions in the menstrual sphere practically to *normal*. Their *statements* are based on 118 cases; most of these tuberculous women were taking a systematic course of tuberculin treatment according to Spengler's technic. Spengler believes that tuberculosis is of the human type in some and of the bovine type in other patients, but that both types *participate in most cases. He aims to treat* the patients with the opposite type from that with which they are infected. In 70 women with *dysmenorrhea out of the* total 118, the improvement in the menstrual conditions occurred with promptness and energy. In 16 out of 22 *women with* severe dysmenorrhea *from the first inception* of menstruation the pains vanished entirely under the *tuberculin treatment*. Still more striking was the return or onset of apparently normal menstruation in 14 cases of amenorrhea. In some cases this effect occurred in one and in others in two or three days *after the first injection of tuberculin*. Eisenstein and Hollos called attention last year to the remarkable cure of dysmenorrhea in 10 women taking a course of tuberculin treatment.

122 Erythromelalgia. (Eritromelalgia o neuralgia rossa.) P. Romeo.

118. **Electrocardiograms.**—Galli *gives an illustrated description* of the method of recording the movements of the heart *by the string electrometer which registers* the electric currents generated in the heart muscle by each contraction. The tracings of these "action currents" form the electrocardiograms, and they afford better insight into the functioning of the heart, it is claimed, than any other means of investigation at our disposal. Einthoven has been mainly instrumental in perfecting this technic.

THE PHARMACOPEIA AS THE STANDARD FOR MEDICAL PRESCRIBING.*

TORALD SOLLMANN, M.D.
Professor of Pharmacology and Materia Medica at the Medical Department of Western Reserve University; Member of the Council on Pharmacy and Chemistry of the American Medical Association.
CLEVELAND, OHIO.

I was requested to discuss a subject which has been much agitated of late, namely, "The United States Pharmacopeia and National Formulary as Text-books in Medical Schools." Taking the title "text-books" literally, my answer would be a very brief negative, for the strictly technical reason that the functions of a reference book and of a text-book are to a certain degree incompatible. The Pharmacopeia must be a book of reference, and can yield this function to no other. I will refer only to the matter of the alphabetic arrangement, which is so eminently impractical in a text-book; but there are many other points which are even more important.

After all, however, the question which really interests the profession is not whether these books should be studied in the original text and binding, but rather, whether they can and should serve as the main or exclusive basis of instruction in materia medica. If so, the manner in which they are presented to the student may safely be left to the judgment of the trained teachers of the subject. Looking at the matter in this way, it assumes a much broader aspect; for the question of the adequacy of the official drugs in medical instruction is identical with the question of their adequacy in medical practice. I have, therefore, preferred to alter the title of my paper so as to indicate the larger scope.

INTEREST IN OFFICIAL DRUGS.

The last few years have seen a most remarkable revival of interest in the official drugs and preparations. The cry "back to the Pharmacopeia" has gone through the land. The Pharmacopeia has been lauded here and there as the panacea for all therapeutic ills. To talk and write about "official prescribing" has become the fashion. Is it a mere fashion? Or does it represent a real sentiment, based on conviction, and in final analysis, on facts? Let us examine into the matter. What is behind this movement? What does the Pharmacopeia mean to us? Is it a mere fetish, whose adoration will affect our purification by some mysterious emanation? Or does it stand for definite ideas and ideals? If so, are they worthy, and are they in fact realized by the Pharmacopeia? These questions must be answered, and in no uncertain manner, before we can afford to give our whole-hearted and unreserved support to this pharmacopeial movement. If we find that the answers are but partly satisfactory, then our support should only be partial, and our main energies should be devoted, not so much to the exploitation of the pharmacopeia as it is, but to making it what it should be.

The inquiry has already begun, in the most practical manner, that of the stern logic of facts. Many men who a few years ago prescribed secret remedies are now turning with the best resolutions to the Pharmacopeia and to the National Formulary to see what these hold for them. These books are being subjected to a test much more severe than that to which they were recently subjected by the Food and Drugs Act. They will have to answer the question, in a practical way, whether they are indeed representative of the medicine of the day—not of a hundred years ago, nor of ten years ago, nor of ten years hence—but of to-day: not of medicine as practiced by the herb-woman, or by the "registered-through-years-of-practice," or by the novelty hunter, but medicine as it is practiced by the intelligent, fairly trained, conservative-progressive practitioner, who represents the average practical ideals of the profession. For, after all, the real object of those who strive for reform is not pharmacopeial prescribing, but scientific prescribing; the use of scientific non-secret remedies, such as the Pharmacopeia is supposed to contain. Whether or not the Pharmacopeia is to be the means of this reform depends entirely on the extent to which it meets these ideals.

VALUE OF THE PHARMACOPEIA TO THE PHYSICIAN.

The usefulness of the Pharmacopeia to the physician is coincident with the usefulness of the remedies which it contains. What most concerns the physician is the selection of the substances which are admitted into the Pharmacopeia. To attain its object so far as the medical profession is concerned, it must in the first place contain the substances which the physicians wish to use. It may be put down as an axiom that the practitioner who does not use the remedy which is best for his patient is not doing his duty. If that remedy is not in the Pharmacopeia, so much the worse for the Pharmacopeia.

In the second place, however, to fully reach its ideals, the Pharmacopeia should be, to a certain extent, educative—it should not be the dump heap of a miscellaneous collection of remedies, good, bad and indifferent, which happen to please the passing fancy of the year of its publication. On the contrary, it should aim to contain only remedies of demonstrated value and superiority. In this way it may guide and lead the practitioner, who will come to it with some confidence that in using

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Pharmacopeial remedies he is indeed using something of value.

This, then, is the test to which the Pharmacopeia is being subjected. It is not necessary to await the outcome, the general results can be foretold, and to a considerable extent forestalled, by timely changes. The truest friends of the Pharmacopeial movement are the first to concede that the present Pharmacopeia can not claim to attain fully these ideals, and that the National Formulary is far from being a perfect guide to scientific prescribing. Setting aside the Formulary for later consideration, let us inquire into those faults of the Pharmacopeia which prevent it from becoming popular with the medical profession. This will necessitate some rather thorough criticism, but I trust that this will be constructive, rather than destructive.

Before entering into this criticism I wish to place myself on record as a sincere admirer of the wonderful amount of reliable information which is collected in this volume, and which makes it one of the most valuable works of its kind. Its defects are caused mainly by the methods used in its preparation; and in the following I wish to suggest to you such plans as will, in my opinion, greatly, if not entirely, eliminate these defects. According to the method of scientific therapeutics, let us inquire into the causes of the deficiencies of the Pharmacopeia and see whether we may not thus arrive at rational remedies.

Why does not the Pharmacopeia of to-day represent more successfully the best of present day therapeutics? Why does it not contain some of the valuable remedies, and why does it contain so much that is obsolete?

The causes seem to me to come under three headings: 1, The principles and methods used in selecting what substances are to be admitted; 2, the veil of secrecy thrown about the proceedings of the revision committee; 3, the long interval elapsing between the revisions.

I shall not aim to point out how these same factors lessen the usefulness of the book as a pharmaceutical standard—this aspect of the question is at least equally important; but, for want of time, I shall confine myself mainly to the medical aspects. From this standpoint, the question of the selection of remedies is at the moment by far the most important; but since it is also the most complex, I shall reserve it for the last.

DISADVANTAGES OF THE PRESENT METHOD OF REVISION.

If I am correctly informed, the present revision committee has aimed to enshroud its deliberations and proceedings with an impenetrable veil of secrecy, so that no one outside of the committee should know what was to go into the Pharmacopeia until the first copy was on sale; and so that no one to this day, three years after the publication, should know what manner of reasoning led to the conclusions which are embodied in this book.

It is one of the most unfortunate results of this very system that we do not even know what prompted its adoption. Presumably it was devised with the object of excluding interference on the part of those who might be financially interested in the decisions. If this was the motive, I would submit that publicity would accomplish the purpose much more successfully than any attempt at secrecy.

On the other hand, this short-sighted policy deprived the committee of the benefits of a public discussion of its contemplated policies. No revision committee can be expected to be perfect and omniscient. Would it not be advisable to throw its decisions and conclusions open to a general discussion before they become fixed and binding, as at present, for ten years? I am not proposing that all the details of the deliberations of the committee should be published—a committee of this kind is entitled to some decent privacy and quiet; this is indeed essential to all scientific work. But I *do* contend that its methods and its decisions should be published from time to time, as adopted; and that a reasonable interval be allowed for discussion, criticism and alteration before any decision is made binding.

I am not so sure whether it would be wise to publish the constitution of the various committees, while the work of revision is in progress—but on the whole I think that this would be the wiser policy. At least, there would be no disadvantage and every advantage in publishing the names of those in especial charge of the different portions of the work after the Pharmacopeia is published.

WHAT INTERVAL SHOULD ELAPSE BETWEEN SUCCESSIVE REVISIONS?

As you all know, the Pharmacopeia is revised every ten years. All the improvements and discoveries which are made in the interim must wait for recognition until the next revision. In other words, the Pharmacopeia is generally from one to ten years behind the time. It is superfluous to point out what this means in these days, when the annual output of research in therapeutics, pharmacy and the allied sciences is measured by volumes. Moreover, any errors which have crept into the book; formulas which are found unworkable; standards which actual trial demonstrates as too strict or too lax—all such matters have to stand unrepealed for a decennium.

This has resulted in the anomaly that the supposed authoritative standard was neither the final authority nor the final standard. This deficiency was rendered so conspicuous when Congress enacted the Pharmacopeia as the federal standard, that the present revision committee felt obliged to take the first step in the right direction by issuing lists of "additions and corrections." The necessity for this supplementary revision is made manifest by the fact that within two years these corrections included 431 changes; or 274, if duplicates are excluded. In the words of the chairman of the revision committee:[1] "That the Pharmacopeia should be revised oftener than once in ten years must be apparent to all, and this subject must claim the serious attention of the next Pharmacopeial convention; but, on the other hand, a constant tinkering with the standards should be avoided."

I agree heartily with both clauses of this statement, although I venture to doubt whether any amount of "tinkering" could unsettle conditions more than the long delay which we have witnessed in the issue of the last Pharmacopeia. This, combined with the strict policy of secrecy, operated to the intent that no one knew "where he was at" in matters pharmacopeial, for at least five years. The excessively short time which was granted for the adoption of the new standard served still further to unsettle conditions. This important matter, incidentally, should be adjusted in advance by the convention and not left to the committee or even to the trustees.

---

[1] Amer. Pharm. Assoc. Bull., ii, 365.

To return to the subject, however, there should be no "tinkering," but only such repairs and improvements as the intervening experience has shown to be necessary. On the other hand, whenever the advisability of a change has been demonstrated, it should be made as promptly as possible. I would suggest that the new revision committee publish its conclusions as soon as they are made, monthly if necessary; that a reasonable interval, at least four months, be allowed for general discussion; that once a year, or oftener if necessary, a supplement be issued, printed in such a way as to be readily detached and inserted into the present Pharmacopeia; that each supplement became official four months after its publication. All this before the next regular "revision" is issued; that when the ground has been fairly covered in this manner—be it three, five or seven years—the "revised" edition be published, which would not be anything essentially new, but only a systematized reprint of the old edition and the new supplements. That the same procedure be kept up until the meeting of the next convention, when the committee would terminate its labors by reporting to the convention whatever changes in general policy their experience would suggest. I am convinced that some such changes must be made if the Pharmacopeia is to become the real standard; but these suggestions should only be adopted with a realization of their full meaning.

This whole subject is one of the most important and far-reaching with which the next Pharmacopeial convention will have to deal, for an affirmative vote will mean a radical reorganization of the present method of revision. It will mean that the revision is to be continuous instead of intermittent; that the revision committee will be in active service throughout its entire term of office; it should mean the concentration of the responsibility on those who have the time and ability to render this continuous service and to do the actual work; it should mean the elimination of any whose services are ornamental rather than useful, political rather than technical; it should mean that the ninth revision of the Pharmacopeia would begin to appear and to be official within one or two years after the meeting of the convention; and that it would not be closed until the meeting of the next convention.

ORGANIZATION OF THE REVISION COMMITTEE.

It appears to me that the present revision committee is too large for effective work and for the proper distribution of responsibility. The present method of selecting the members of this committee, without regard to their special qualifications and of subsequently assigning to them special technical subjects, also seems to me poorly adapted to securing the special expert talent which the revision requires. The fact that thus far the revision committee has met the demands on it as well as it has, seems to me rather a fortunate accident. The matter is far too important, however, to be entrusted to accidents. As to the division of the work among the committee, the scheme described by Professor Rice[2] is admirable in its general scope, although I would suggest the consolidation of several of the subcommittees, for the purpose of centralizing responsibility.

To illustrate the working out of the ideas which I have presented, I would submit to you the following outline for the appointment and *modus operandi* of the general revision committee.

Membership of the Revision Committee.—The final voting power should be entrusted to a limited "executive committee" consisting of the general chairman and chairman of the nine subcommittees, namely:

1. Admission.
2. Pharmacognosy.
3. Proximate Principles and Assays.
4. Volatile and Fixed Oils.
5. Inorganic Chemicals, Chemical Processes and Reagents.
6. Organic Chemistry (including synthetics).
7. Pharmaceutical Processes and Formulas.
8. Pharmacodynamics (including sera).
9. Therapeutics (including strengths and doses).

With the general chairman, this would give a working (executive) committee of ten members. These chairmen should be elected directly by the pharmacopeial convention. Two nominations for each place should be submitted by the retiring revision committee—one of these two nominations should be that of the present incumbent, if he has performed his services satisfactorily, and is willing to continue. Additional nominations from the house should be called for. The nominations and ballot for each place should be taken up seriatim.

The elected chairman of each subcommittee should appoint such "associates" to his committee as he deems advisable, subject to the approval of the executive committee. The associates of the admission committee, however, should be elected directly by the convention. In case of failure of any member to carry on the work of his committee properly, it should be the duty of the general chairman to report this to the trustees, who, after opportunity of hearing, should relieve him of further service, if they deem this necessary, and elect a successor from nominations made by the executive committee. Vacancies from other causes should be filled in a similar manner.

GENERAL WORKING METHOD.

The admission of an article having been decided by the admission committee—of which I shall have more to say presently—the general chairman should refer the article to the chairman of one of the committees 2 to 8, on whom the responsibility of securing a proper description should rest. The chairman of this subcommittee should then apportion the article among his staff and should obtain what outside aid he needs from the other subcommittees and elsewhere, and render a report to his subcommittee for discussion. After alteration and adoption by this subcommittee, he should transmit his final report to the executive committee for vote. If adopted, the therapeutic committee should affix the dose, and the general chairman should prepare the description for publication, submitting proof to the executive committee and to every member of the subcommittees in which the report originated.

SCOPE OF THE PHARMACOPEIA AND THE ARTICLES ADMITTED.

I have postponed the discussion of this question as long as possible, because it is the most difficult phase of the subject. We will make better progress if we acknowledge at the outset that the question is incapable of a strictly scientific and logical solution; that the answer must be a compromise, because the Pharmacopeia itself is a compromise between very diverse interests.

---

[2] Pharm. Era, 1895, xiii, 102.

The retail pharmacist, the manufacturer, the unprogressive and the progressive physician, and the pharmacologist—each would make a very different Pharmacopeia. The east and the west and the south would introduce further differences. No one Pharmacopeia which human ingenuity could devise would seem ideal to all of these factions. Admitting then this difficulty, that the Pharmacopeia must be a compromise, it does not, however, follow that it must be a compromise without any plan or system.

As a basis for discussion, I would submit the following definition of the plan and scope of a national Pharmacopeia, viz:

It should aim to enumerate those substances whose medicinal value and superiority are generally conceded and which are generally used in the country; it should aim to furnish such descriptions and indicate such tests as will suffice to establish the identity, strength and medicinal purity of these substances; and it should furnish practical working formulas for such preparations as may be profitably prepared in a well equipped retail pharmacy. It should aim to present this information clearly and conveniently; above all, it should aim at the highest degree of reliability of all its contents. Consequently, it should be slow to accept any statement or opinion. It should breathe a healthy but not excessive conservatism as to new matters, and an equally rigorous criticism and re-examination of old matter.

With this general definition in mind, let us examine what criteria should be applied to the selection of admissions. The extremely conflicting opinions which prevail on this score can, it seems to me, be brought under three headings:

1. The first opinion, particularly prevalent among pharmacists, is that the Pharmacopeia should contain all substances which are sufficiently often used; whether they be good, bad or indifferent; whether they are used by physicians or only by the laity.

2. The second opinion differs from the first only in so far as it would exclude those substances which are not used by physicians, but only by the laity.

3. The third would exclude all substances whose value had not been scientifically demonstrated, regardless of their extensive use.

Personally, I feel convinced that the last is the direction in which progress lies. It is the ideal for which we should strive; the ideal which will enlist the sympathy of the best, and I trust of the largest, portion of both professions. In proportion as it is successfully attained, it will do more to place the popularity of the Pharmacopeia on a solid foundation, among the medical profession, than any pandering to ephemeral fads and fancies, than any concessions to "nine day wonders" of advertising.

In urging you to accept and support this ideal, I do not wish to commit you to any visionary scheme, to any impractical standards. I do not consider the full attainment of this ideal practical, but I do consider the striving for it as eminently practical and useful. An ideal, however worthy, is not in itself the solution of a problem, but it can be of great practical value as a guide in the solution. The compass does not calm the tempest; it does not even steer the mariner across the sea—but it shows him in what direction to steer.

HOW TO DETERMINE WORTH.

If we then accept this ideal, how are we to determine which remedies are truly worthy? There are three different ways open to us:

1. Popular experience as determined by the continued extensive use of the drug.

2. Clinical experience, as represented in the current opinions of clinicians.

3. Laboratory experience, representative of the stricter conditions of control.

Each of these methods is open to obvious fallacies. Mere popularity, as evidenced by extensive use, is no more conclusive evidence of the intrinsic value of a remedy than it is of the intrinsic value of anything else.

The clinical experience would seem the best guide, theoretically. But no one who has watched the ebb and flow of therapeutic practice—the ease, for instance, with which it can be temporarily swayed by skillful advertising—would care to entrust the judgment of therapeutic value to clinical experience alone.

The laboratory investigator, finally, deals more strictly with demonstrable facts; if he is honest and capable, his statements as to these facts may be generally accepted as correct and conclusive. But the honest and capable laboratory investigator is the first to concede the limitations of these facts and to seek their correlation with clinical and popular experience.

I believe that the practical solution of the problem lies in the last direction—in the critical correlation of the three classes of experience. With the present imperfections of therapeutic science, the problems must be approached by every avenue, and not by one to the exclusion of the others. Popularity, or the lack of it; the consensus of clinical opinion; and laboratory results—each of these should be admitted to furnish presumptive evidence for or against the value of a substance, unless they are clearly and definitely contradicted by the others.

If we are agreed on the ideal and on the nature of the evidence required, we must next ask, how is the evidence to be collected and judged? As to the collection of the evidence, the methods must be very different for each of the three classes. The simplest case is in regard to laboratory experience; for the number of professional "pharmacologists" is so limited that their opinions could be readily learned by direct correspondence.

The same method, however, when applied to clinical and popular experience, would only result in confusion. It would be necessary to aim at a representative rather than at a universal expression of opinion. For this the ideal medium exists ready at hand in the local societies, both medical and pharmaceutical.

In practice, then, I would suggest that a check list of the substances and preparations contained in the present Pharmacopeia be sent to the secretary of every local medical and pharmaceutical society, with the request that his society vote which of these articles they consider worthy of retention, in accordance with the ideals laid down; and to indicate any further remedies which they would wish to have added.

If a fair proportion of both professions can be made to see that the Pharmacopeia is, after all, their book, and not the book of the revision committee; if they can be made to feel that their cooperation is really desired and that the request for cooperation is not merely perfunctory; then I feel certain of a sufficient response to such an inquiry to furnish some statistical basis for judgment. This would be of the highest value, indeed indispensable, for the solution of this question, provided that it is used intelligently and judiciously, with a proper regard for cause as well as effect.

This opens up the final question as to who is to sift and judge this and other evidence and decide on the admissions. At present, I believe this matter is decided by the whole revision committee, each member having an equal voice. Is this method calculated to give the best results? In seeking for an answer we need only consider the fact that most of the members of this committee are supposed to be selected primarily for their expert knowledge of chemistry, pharmacy or pharmacognosy and not for their ability to judge of the medicinal importance of the substances. It undoubtedly happens quite frequently that the knowledge of the one and the ability to judge the other are combined in the same individual; but even so, this is little more than a coincidence; and this matter also is far too important to be left to mere chance.

This is illustrated by the examination of the composition of the revision committee. Every one, I think, will concede that the medical profession should, on the whole, have the larger, if not the exclusive share in deciding what substances are of medicinal importance. Yet of the twenty-six members of present revision committee, only twelve have the title of M.D, and of these only half are identified mainly with medicine. So that the medical profession, instead of having the dominant voice in the decisions, is very decidedly in the minority. This preponderance of pharmacists is indispensable for the technical work of the revision, for this is mainly pharmaceutical. This makes it apparent that these two subjects—the selection of the admissions and the technical matter—can not be handled with equally satisfactory results by the same set of men. The authority and responsibility for the admissions must be vested in a special committee—and the importance of this subject demands that this committee be elected for this specific purpose directly by the convention.

I can see no valid objections to this plan; any members elected to this committee could also be elected to the chairmanship of any of the other subcommittees if this were thought desirable. To secure a good committee, however, the convention should be guided by definite rules as to eligibility. It goes without saying that the members should be of the highest integrity and as free as possible from any affiliations which might cloud their judgment. But it is equally important that they should be able to deal intelligently and thoroughly with the subject, and to this end, that they represent fairly the best sanely progressive and conservative element of both professions.

The exponents of popular, clinical and laboratory experience should all three be represented by retail pharmacists, practicing clinicians and professional pharmacologists. An equal representation appears to me the most desirable, let us say two representatives of each, making a working committee of six. After due consideration and discussion of the statistical and other evidence, an affirmative vote of four should then be required for the admission of an article. As soon as an article has been thus accepted, it would be turned over to the general chairman of the revision committee for technical elaboration, as I have previously outlined.

There is one more matter in connection with admissions where the present policy should be revised—I refer to the admissibility of patented medicines and otherwise protected articles. The policy, dictated by the convention, has been to exclude these from the Pharmacopeia, presumably as a protest against the commercialization of what we would love to see an honored sister-profession, rather than a business. If this was the object of the exclusion it has signally failed in practice—the new inventions are still being given to the suffering public with a monopolistic string attached—free handed, but not free! Much as we may deplore this fact, a fact it remains. To refuse to utilize a therapeutic improvement in this account would be to cut off the patient's nose to spite the promoter's face. And if we use them there is little sense in excluding them from the Pharmacopeia. So long as we prescribe his wares, the promoter cares very little whether we give them official recognition. On the other hand, admit the best of the strictly scientific protected articles of each class to the Pharmacopeia, making exclusively pharmacopeial prescribing a practical possibility instead of a Utopian theory, and you will have made it an object to the promoter to be strictly scientific, by giving him a real advantage over his unscientific competitors.

It may be urged that this is unethical; that it would overload the pharmacopeia; that it would hold out too strong financial inducements. To these objections I would reply that there is no violation of the principles of scientific ethics and that altered circumstances alter practical ethics. Much of the dreaded overloading might be saved, here as elsewhere, by group-headings; and, after all, the number of important "discoveries" which would survive a careful, scientific scrutiny and discounting of any fictitious value of advertising, and of the lure of novelty, is not so large as to excite alarm—at least my service on the Council on Pharmacy and Chemistry of this Association has so impressed me. And it has also impressed me with a healthy optimism as to the probable attitude of such a committee toward outside influences, especially when the responsibility could not be hidden behind secret deliberations or behind a large committee. I may add that this suggestion is not at all revolutionary, for it was publicly advocated by Professor Rice in the admirable paper to which I have already alluded.[2]

THE NATIONAL FORMULARY.

Until quite recently the National Formulary was a modest, unobtrusive, harmless and really useful little book, compiled by the American Pharmaceutical Association primarily for the benefit of Pharmacists, purposing to give working formulas for such preparations as the pharmacopeial revision committee did not care to father—elixirs, cough syrups, shot-gun prescriptions, etc.—a book in which the tottering great-grandmothers of the materia medica were resurrected from their well-earned sleep in the therapeutic graveyard, to join in a merry dance with the lusty and vociferous youngsters of the modern therapeutic yellow press; with here and there a healthy débutante waiting bashfully for the favorable notice of the revision committee.

Altogether, the spirit of the book adhered pretty closely to the motto: "For those who like this sort of thing, this is just the sort of thing they like." This was the kind of unpretentious, irresponsible but useful existence from which the National Formulary was suddenly roused by its federal recognition as a legal standard. It had aimed at nothing higher than to supply a popular demand, uncritically and blindly; and suddenly found itself set up as a leader for this very demand. The position is in many ways highly anomalous. These are problems, however, which do not concern the medical profession and that is my principal reason for pointing them out.

There is no doubt that preparations such as those listed in the National Formulary are used by the profession as well as by the laity; and thus there is a legitimate need for such a book, which it well meets. There should be definite and legalized standards of strength for such preparations, although the working formulas and flavoring of the National Formulary should in practice be made optional with the manufacturer. To this extent the National Formulary deserves encouragement, and if the American Pharmaceutical Association so desires, the American Medical Association could authorize the Council on Pharmacy and Chemistry to act as an advisory committee to whom such questions as doses, the desirable strength of mixtures, or obvious therapeutic incompatibilities might be referred. Further than this, however, we should not go. The medical profession should emphatically decline to share in the responsibility for a book so professedly uncritical as the National Formulary, by its very nature, must be.

In conclusion, I feel very sincerely that I must ask pardon for my presumption in occupying so much time in the discussion of matters in regard to which I am distinctly an outsider. I wish to assure you, however, that I did not undertake the matter lightly, but after much serious thought and hesitation, not because, as Professor Remington has said, "If any man wants a subject for discussion, and one which he can hit with safety, there is always the Pharmocopeia." My motive has been the conviction that all the preaching in the world will not and can not make the Pharmacopeia the practical standard of medical prescribing so long as the revision committee adheres to its present ideals and methods. The ideals and methods which I have laid before you can only be realized by the practical cooperation of the medical profession. In less than two years the pharmacopeial convention meets. If you agree with all or part of what I have said you have a personal duty to discharge, and it was the sense of my own share in this duty which has prompted me to address you on this subject. My personal inclination would have been for almost any other subject.

Experimental Reproduction of Whooping Cough.—W. N. Klimenko reports in the *Centralblatt für Bakteriologie*, Oct. 10, 1908, that he has succeeded in cultivating the Bordet-Gengou bacillus from the catarrhal secretions of children with whooping cough, and with it has reproduced the disease in 48 young dogs and in monkeys, afterward cultivating the bacillus again from the secretions of the animals. It was in 1906 that the Belgians, Bordet and Gengou, announced the discovery of a bipolar bacillus in the first week of pertussis, which they regarded as the causal germ. Klimenko found this same germ in 80 per cent. of 76 children in the first week of whooping cough, while the findings were constantly negative in 50 healthy infants and in patients with other various affections. The period of incubation in the experimental pertussis ranged from two to six days, and the duration of the disease averaged 48 days. Bordet found a specific amboceptor for this bacillus in the serum of children convalescing from pertussis.

THE NEED OF MORE INTIMATE KNOWLEDGE OF THE U. S. PHARMACOPEIA AND THE NATIONAL FORMULARY AMONG PHYSICIANS.*

JAMES M. ANDERS, M.D., LL.D.
Professor of Medicine and Clinical Medicine in the Medico-Chirurgical College.
PHILADELPHIA.

There is need of a sober viewing of the question of pharmacy in its relation to medicine. While these two professions are engaged to an extent in different fields of observation and practical work, they have many interests in common, and it is especially in behalf of those higher ethical principles on which real progress depends that joint meetings and free discussions of the natural lines of contact will prove mutually strengthening and result in a real gain to mankind. Indeed, the program of procedure has been already outlined, and men with definite convictions, beliefs, hopes and aspirations for better things, have enlisted in the movement under the general direction of the American Medical and American Pharmaceutical Associations, and it is fitting that this section should have been fixed on as one of the principal centers for the consideration of subjects affecting so vitally the present and future welfare of both medicine and pharmacy.

I realize that the subject which I am about to discuss must be approached carefully and calmly, and also that in emphasizing the importance of the utilization of the U. S. Pharmacopeia and the National Formulary in the practice of medicine, nothing is to be gained by extravagant claims or unreasonable statements. I can only hope (and I believe) that the result of my recent experience and investigations into the question may be of assistance to other practitioners. Admittedly, no member of our profession is deserving of censure who honestly strives to bring to his aid in the treatment of disease all the therapeutic adjuvants at his disposal. He should, however, make thrice certain that he is weaponed with reliable instruments. Such a course would exemplify a proper appreciation and respect for scientific pharmaceutics. The time has come to recognize the fact that a reform movement among pharmacists is now, and will be as time passes, in progress, working through the American Pharmaceutical Association and its numerous branches. A parallel movement with a view to meeting the requirements of the higher ethical standards and improved conditions generally in the medical profession has been brought about in recent years, chiefly through the efforts of Dr. George H. Simmons, editor of The Journal, Dr. Frank Billings, Dr. McCormack and other individual members of the Association, the work of the Council on Pharmacy and Chemistry, and of the Council on Medical Education of the American Medical Association, and the passage of the federal Food and Drugs Act.

It is safely within the limits of strict justice and truth to remark that legitimate pharmacy has been grossly neglected by the medical profession during the past quarter of a century—a period during which physicians have been depending largely on proprietary preparations and "secret nostrums," and in which there has developed a stolid indifference to ethical obligations. The propaganda in favor of the U. S. Pharmacopeia and National Formulary will be productive not only of cordial relations between these two professions, but through their collaboration the warfare already begun will be carried to a victorious issue. The ultimate aim of such a union of forces should be to overthrow, by effective legislation and in other ways, all quackery, charlatanism, the "club practice" evil, unethical proprietaries and secret nostrums. To this end there should also be a public awakening—a prevailing demand for absolute publicity as regards the composition and therapeutic application of the physician's armament.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

In general, education of the medical profession in the importance of the information to be derived from a careful study of the U. S. Pharmacopeia and the National Formulary is a leading consideration and one which should not be ignored. It is certain that the advantages to be gained from such a course in the past have not been appreciated, principally because of the prevailing ignorance in regard to the contents of these authoritative works. Indeed, the present unenviable situation and the shortcomings of the medical world in relation to pharmaceutics are largely the result of the errors of the past, especially in the direction of a dominating tendency to employ proprietaries and secret nostrums. The profession had lost sight for a considerable interval of time of the successive achievements of the geniuses to which the science of pharmacy owes its being. For their wisdom and the unselfish, steadfast devotion of superior endowments to the highest interests of the medical profession, these men are worthy of the most distinguished recognition.

It may, however, be justly claimed that at present the medical profession of America is slowly and gradually recovering from the debauched condition into which it had fallen in consequence of the wide use of proprietary remedies, and what is even more regrettable, illicit combinations between certain of its members and those manufacturing druggists who pursued dishonorable methods.

The time, therefore, is ripe for direct, pointed statements concerning the lack of studious attention on the part of the medical profession to the U. S. Pharmacopeia and the National Formulary. If physicians were to inform themselves more fully on the reliable facts and data contained in these books they would appreciate their superior advantages in practical therapy. It is universally admitted that the U. S. Pharmacopeia has been edited and revised by men who by training are entirely competent to accomplish the task in a thoroughly scientific, trustworthy and acceptable manner. Its teachings form one of the truly important foundation-stones of rational therapeutics.

Physicians may rest assured that the preparations to be found in the U. S. Pharmacopeia are to be preferred, as a rule, to the newer, untried, unofficial preparations exploited by pharmaceutic chemists and manufacturers. On the other hand, there are certain synthetic proprietary articles in general use and widely approved by the best element of the medical profession; and a selected few of these might be advantageously introduced into the U. S. Pharmacopeia.

The adequate training of the physician of the future will demand an acquaintance with the contents of the volume under consideration. "The undergraduate's knowledge of the subject-matter need not extend beyond a complete summary, but this he should have with a view to stimulating his subsequent interest in this branch of practical medicine. In medical schools in which the professors of materia medica and therapeutics are authors of works on these subjects, it is proper and advantageous for the students of such schools to adopt them as text-books, but under these circumstances teachers should avail themselves of the opportunity to force conviction on the minds of students as to the importance of the U. S. Pharmacopeia as a work of reference and post-graduate study. I have examined carefully the catalogues of the regular medical colleges of this country, numbering 144, and found that of these sixteen have recommended the U. S. Pharmacopeia, while one mentioned the National Formulary."[1] The figures indicate conclusively the lack of sentiment among medical educators favorable to the important matter of instructing students of medicine "as to those portions of the U. S. Pharmacopeia which are of value to the practitioner." The adoption of measures to bring about a more general use of this work in the training of undergraduates is to be advised and encouraged. It is gratifying to record that at an informal conference called by Prof. J. P. Remington of the teachers in the medical schools of Philadelphia, the following resolution was passed:

> *Resolved*, That it is of the utmost importance for accuracy in prescribing, and in the treatment of disease, that students of medicine be instructed fully as to those portions of the United States Pharmacopœia which are of value to the practitioner, and that members of the medical profession be urged to prescribe the preparations of that publication, and, further, that this resolution be forwarded to the medical and pharmaceutical journals, and to the teachers of medicine and therapeutics in the United States.

The motto for the recent graduate should become "Publicity and open dealing, the while prescribing the preparations of the U. S. Pharmacopeia."

I am ready to grant that natural conditions and means are assuming more and more importance in combating human ills. And while drugs have been practically abandoned in the treatment of certain diseases, notably tuberculosis, they have a distinct sphere of usefulness; and the decadence of the use of drugs on account of the rapid progress made by the science of hygiene in recent times is no good reason for careless ness and indifference in regard to their quality and ability. The medicinal agents employed by the physician then still form an important part of the physician's armamentarium, so long as he can depend on their proclaimed composition. It is obvious that from this point of view too little intelligent discrimination has been exercised in the selection of medicines in the past. Hand in hand with the progress of knowledge concerning the action of drugs on the human economy must go definite and accurate knowledge of the composition of the substances used in the treatment of disease. It is in this connection that the U. S. Pharmacopeia and National Formulary would contribute materially to future medical progress if they were made the subject of universal study and consideration among the physicians of the United States. It is earnestly hoped and believed that the rational outcome of the present movement which seeks to abandon indefinite, uncertain and variable preparations, will effect an increasing tendency to the use of the more reliable and unchanging preparations of the U. S. Pharmacopeia.

---

[1] Anders, J. M.: The United States Pharmacopeia from a Physician's Standpoint: Monthly Cycl. Pract. Med., May, 1908.

As a means of familiarizing physicians with these works I would strongly recommend future joint meetings between the many branches of the American Pharmaceutical Association and local medical societies. United action, if properly directed and maintained, would serve to promote materially the interests of scientific pharmacy. We have arrived at an era in the history of American medicine at which the trained pharmacist and the physician can each render important service to the profession of the other if granted a favorable opportunity.

Moreover, it is fitting that the medical profession should pay just tribute to the significance of the service which the National Formulary is rendering both to practitioners and to the larger public.

I find that many physicians are not acquainted with the contents, objects and meaning of the National Formulary. For the benefit of this class it may be pointed out here that this neat volume contains many excellent formulas for preparations, none of which have been as yet introduced into the U. S. Pharmacopeia, but which were formerly made after different formulas (in different sections of the county and also in the same city), and have come into established use, but have been brought, after much experimentation and labor by the committee on National Formulary of the American Pharmaceutical Association, to a common, authoritative standard. The above-named committee having accomplished the stupendous task set before it with success, it behooves the medical profession to cooperate whenever possible by accepting the formulæ contained therein, "instead of designating any special maker's product." It is not my intention to advocate the use of the National Formulary to the exclusion of prescriptions written at the bedside to meet the indications presented by individual cases, to which preference is to be given in the majority of cases.

It may well be asked why learned members of the profession should permit the use of their names by manufacturers of preparations foisted on the market solely for commercial reasons. Again, why should the information given to the medical profession by these manufacturers be regarded as authoritative and convincing by the rank and file of the profession? Wiley[2] has well said:

> We have reached a stage in the evolution of therapeutics and practice in which the physician can take a firm stand. There are plenty of remedies of known character to employ his entire skill and to furnish the munition of his therapeutic armament. There can be no excuse, therefore, for the recommendation or prescription of the secret, fake or unknown proprietary remedy.

In this connection of particularly evil omen for the attainment of this most desirable state of affairs is the strong tendency, already emphasized, to prescribe proprietaries. Physicians are too apt in prescribing to be controlled by motives of convenience, using the remedies that are brought to their attention and exploited by convincing hired agents, instead of taking the precaution and trouble to acquaint themselves fully with the official preparations so abundantly to be found in the United States Pharmacopeia and National Formulary. As a means of counteracting this subtle, widespread, yet influential tendency, a more intimate knowledge of the contents and aims of the United States Pharmacopeia and National Formulary would, I strongly believe, prove efficient.

The intention of the present paper is not to present a laudatory account in ornate phrases of the works under discussion, but rather to eradicate the curious notion which numbers of physicians of this country have that what is of first-rate therapeutic value is to be found outside, among the newer, unofficial preparations. If physicians could be induced to devote more of their energies to the study of the remedies that have stood the test of time a more healthful, robust, therapeutic tone would be the inevitable result. I am pleading for a spirit of unity among the members of the American Medical Association regarding this important question.

THE PHARMACOPEIA AS A LEGAL STANDARD.*

H. W. WILEY, M.D.
Chief, Bureau of Chemistry, U. S. Department of Agriculture.
AND
L. F. KEBLER, M.D.
Chief, Drug Division, Department of Agriculture; member of the Council on Pharmacy and Chemistry of the American Medical Association.
WASHINGTON, D. C.

Many years before the publication of the first edition of the United States Pharmacopeia it was recognized by the leaders of the medical and pharmaceutical professions that standards for potent well-known drugs were highly desirable, if not absolutely necessary for the proper treatment of human ailments. Tangible evidence of this feeling was manifested by the publication of a number of books by various authors which contained standards or descriptions of drug products of much value. The first edition of the Pharmacopeia appeared in 1820 and was immediately voluntarily accepted as the proper guide by both professions. Successive editions appeared decennially; and Congress in 1848 recognized this authority as the legal standard for drugs imported into the United States in the following language:

> If, on examination, any drugs, medicines, medicinal preparations, whether chemical or otherwise, including medicinal essential oils, are found, in the opinion of the examiner, to be so far adulterated, or in any manner deteriorated, as to render them inferior in strength and purity to the standard established by the United States, Edinburgh. London, French, and German pharmacopeias and dispensatories, and thereby improper, unsafe, or dangerous to be used for medicinal purposes, a return to that effect shall be made on the invoice, and the articles so noted shall not pass the custom-house, unless on a reexamination of a strictly analytical character, called for by the owner or consignee, the return of the examiner shall be found erroneous, and it is declared as the result of such analysis, that the articles may properly, safely, and without danger, be used for medicinal purposes.

The necessity of thus recognizing the Pharmacopeia had been emphasized by numerous investigations of medicinal agents which showed that a great number of inferior articles were imported into the United States. These examinations were largely stimulated by the activities of the Philadelphia and New York colleges of pharmacy. The latter repeatedly called attention to the fact that large quantities of sophisticated and misbranded chemicals and pharmaceutical preparations were being daily imported. Attention was also called to the fact that a great variety of inferior drugs were passing the custom-house and that every possible effort should be made to prevent their introduction into this country. An examination of the conditions then existing showed that this country was considered the dumping-ground of Europe.

---

[2] The Journal A. M. A., Nov. 9, 1907.

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Soon after the enactment of the above law it was found that there was a lack of standards or methods for determining standards which made it difficult for the customs officials to enforce the law judiciously and satisfactorily. The descriptions contained in the Pharmacopeia were not sufficiently accurate and detailed to cause the detention of certain drugs of inferior quality; the construction of various sections of the book was not the same at the different ports; consequently action was not uniform.

On learning of these difficulties the various members of the pharmaceutical profession decided to assist in adjusting these annoyances by calling a convention of the colleges of pharmacy in New York City. The general belief prevailed that the law was ample to regulate the admission of adulterated drugs, but that additional standards were required. After full discussion the convention adopted standards for ten drugs which were forwarded to the Secretary of the Treasury with the recommendation that they be generally adopted so that uniformity would obtain at the various ports. These standards were accepted and proved highly beneficial.

This is the beginning of the adoption of actual legal standards for medicinal agents in this country. These standards proved highly beneficial and provided stimuli for the formulating of standards of other drugs and enlarging the scope and usefulness of the Pharmacopeia. During the past twenty-five years many state laws have been enacted which prescribe the Pharmacopeia as a legal standard. With few exceptions, however, little attention was given to drugs by state officials, and manufacturers and dealers were indifferent to the standards contained in this book and the activities of the state authorities. Many dealers advertised their own standards, which were arrived at by methods known only to themselves, thus making it very difficult for analysts to obtain the same results as those claimed.

June 30, 1906, this excellent authority of standards for drug products was officially recognized by the Congress of the United States in the passage of the Food and Drugs Act. Soon after its enactment the standards and methods of the Pharmacopeia were critically examined and tested by all affected. Defects, inconsistencies, unreasonable and improper standards were found in abundance. Never before was so much interest displayed or a book so critically studied. Numerous changes were insisted on and great pressure was brought to bear on the committee of revision by correspondence, personal interviews, etc., with what success can readily be seen by the number of corrections printed a year ago. Some of these changes were undoubtedly desirable, but in some cases the standard was materially lowered, and in other cases the tests were modified so as to render them inefficient. For example, it has been found that the modified test for detecting gurjun balsam in balsam copaiba is so inexact as to permit the adulteration of the latter with at least 35 per cent. of the former without the possibility of detection. Excellent as are some of the standards and descriptions contained in the Pharmacopeia, it should be pointed out that in many cases no provisions are made for excluding or permitting the admixture of any stems, sticks, sand or other extraneous and inert material with leaves, berries, bark or seed in either the whole or powdered state. For example, it is common to find from 15 to 20 per cent. of sticks and stems mixed with buchu leaves. The same is true of cubeb berries. Powdered drugs are adulterated with large amounts of sand, ground olive stones and inert foreign plant tissue. The adulterations in all cases here considered are so gross as to preclude the idea of accidental admixture. Various roots, seeds, leaves, etc., are at times mixed with inferior and spurious roots, leaves, seeds, etc. To what extent these foreign and inferior articles modify the physiologic action of the drug is undeterminable. The question frequently arises as to the advisablity of permitting the use of such admixtures. It is certain that if a preparation made from a crude drug of fine quality possesses certain therapeutic properties, the same physiologic action could not be expected from a product made from drugs sophisticated in devious ways. As an example, digitalis leaves of the second year's growth possess well known therapeutic properties, but the leaves of the first year's growth are supposed to be devoid of any material activity and the question naturally arises whether it is wise or advisable to deny entry to an importation consisting of a mixture of both of the above named leaves. In our opinion nothing should be left to chance with so important and valuable an agent as digitalis. No physician knowingly would jeopardize the life of his patient by employing this drug or any preparation made from it which he had any reason whatever to believe in any way deficient. He prescribes on the basis of a pure, efficient drug.

While the same argument may not apply with equal effectiveness to some other drugs, it is apparent that the therapeutic action would be modified to the extent that the drug is adulterated or of inferior quality.

Section 11 of the Food and Drugs Act reads in part as follows:

> " . . . and if it appear from the examination of such samples that any article of food or drug offered to be imported into the United States is adulterated or misbranded within the meaning of this act, or is otherwise dangerous to the health of the people of the United States, or is of a kind forbidden entry into, or forbidden to be sold or restricted in sale in the country in which it is made or from which it is exported, or is otherwise falsely labeled in any respect, the said article shall be refused admission. . . ."

The personnel of the Pharmacopeial Committee of Revision is such that their final acceptance and fixing of a standard for any drug product should be final. Any other construction placed on this authority would lead to endless confusion.

Under the above quotation from Section 11 we are firmly of the opinion that any article recognized by the United States Pharmacopeia which deviates from the standard set by this authority is improper, unsafe and dangerous for medicinal purposes, except in such cases where the product is used in the manufacture of articles which are subsequently standardized, or for the manufacture of certain definite principles, such as strychnin from nux vomica. Even in cases where the crude drug used in the manufacture of the preparations which are subsequently standardized is so debased or of so low a standard as to preclude its use in the manufacture of pharmacopeial products it will not be considered as coming within the limits of the above statement. We are further of the opinion that a drug product which is forbidden to be sold or restricted in sale in the country in which it is manufactured or from which it is exported should be refused admission to the United States under this section. Any drug which is not good enough in the country of production or exportation for the treatment of its own people is certainly not satisfactory for a medicinal agent in the treatment of the people of the United States.

At present both the medical and pharmaceutical professions are making strenuous efforts to eliminate from their medical armament worthless and questionable remedies and are constantly turning their attention to the pharmacopeial products. The claim is frequently made that articles prepared according to the methods and formulae described by the Pharmacopeia are not uniform and it is believed by many that this non-uniformity is largely due to the initial character of the crude drugs used.

RESPONSIBILITY OF THE MEDICAL PROFESSION FOR THE USE OF NOSTRUMS.*

C. F. WAHRER, M.D.
FORT MADISON, IOWA.

In speaking of the shortcomings of the profession to a colleague some time ago he remarked, "Don't abuse the profession; we get enough of that from the old women and other enemies, most of which is unjust; but where it comes from you it comes doubly hard." My answer was and still is, we must begin reforms among ourselves before we attempt reforms among others, and as long as we repeat our sins my motto is: "Lay on Macduff!" Before we sweep other people's premises let us clean up at home and stay clean. There are but few of us who do not know the evils of the nostrum trade, both to ourselves as well as to the poor victims who suffer from it, yet do we not aid and abet this very evil? While there are but comparatively few of us who openly prescribe or dispense the so called "patent medicines," such as Jayne's Expectorant, Ayer's Cathartic Pills, Harter's Iron Bitters, or Pink Pills for Pale People, yet I heard a regular physician once lay great emphasis on the value of McLaine's Indian Root Pills or Wright's New Life Pills, both of them rank nostrums. There are thousands of doctors all over our country who prescribe or dispense stuff no better in quality and no better as far as the secrecy of the preparation is concerned.

It is a sad but too true comment when I say that more than half of the medical profession—including the best there are, professors in medical colleges even—prescribe remedies, the composition of which they are absolutely ignorant. Why do they do it? Is it because they are taught to do so while attending medical college in their studies in pharmacology and therapeutics? No? Why, then? It is because pamphlets and samples distributed by a wily, smooth-tongued detail man, who has learned to say his piece, has drummed this perverted system of therapeutics into vacant brains. It is like selling gold bricks or oil stocks; one man says thus and so, and one hundred men believe him.

When these "easy marks" look for the formula they don't find it—or find only a part of it, something like the following: Each ounce represents (not contains please remember, it *represents*) the active principles of peruvian bark, columba, crampbark and numerous other ingredients with aromatics so combined as to form a palatable preparation of the highest efficiency for the cure of all ailments of women, and it is especially useful in dysmenorrhea, amenorrhea, menorrhagia, metrorrhagia and all ovarian and other sexual irregularities and disturbances. Now, isn't this just what we all need and what we have all been looking for?

Well, it will sell; hundreds of physicians will buy it and try it on their patients, because the manufacturer sends samples prepaid or sends his salesmen, who say they are selling lots of it and that it is a good seller. Dr. Jones of Smithville has given an order for twenty gallons of it—and Dr. Smith of Jonesville wouldn't do without it and he is "making money hand over fist" out of it. While he is talking and getting the medical man jealous of Smith and Jones the physician forgets all about asking what the stuff is made of. Now I will ask: Who made and devised this wonderful formula? And in case the physician did ask or write for the formula he was merely told each ounce *represented* so much of so-and-so. For instance, to show how "muddling clear" this all is: Opium may be represented by morphin, narcein, dionin, codein, meconin, heroin, thebain or one or two or more of them! How would apomorphin do, for instance? Is digitalis represented by digitalin, digitalein, digitoxin, digitonin or what? I presume principally by what! And that will answer the purpose, will it?

But this is not the worst by any means. What does your patient get when you give him antikamnia? The company in St. Louis tells you *anti* means *against*, and *kamnia* means *pain;* so you are giving something that means pain killer. But I ask again, what is it? You don't know, yet you use it in your practice and advertise it, because every tablet has "A K" on it "so you will know that it is the genuine." I dare say more of this heart poison has been prescribed by the rank and file of the profession and medical college professors, who wrote testimonials endorsing it, than all other semi-proprietaries combined, yet no man knows to-day what's in it so far as their literature reveals to us. Aren't some of us ashamed, and if not, why not? I said no one knows what's in antikamnia. By analysis we are fairly sure that before the enactment of the Food and Drugs Act it contained in various proportion acetanilid, sodium bicarbonate, caffein and probably some citric acid. But now they are compelled by law to state that each package contains a certain amount of acetphenetidin, the pharmacopeial name for phenacetin. They also combine it with quinin, so you can write a prescription for "A K & Q," also with codein, so you can tell your patient to go to a druggist and get a dozen of "A K & C," etc.

How many times do you suppose any of your bright patients will return to you and pay you for telling them, or prescribing for them, those wonderful tablets with "A K & C" on them, that cured their headaches or coughs, or rheumatic pains, or moved their bowels, when they took "A K & C" with cascara? Not very often, when all they need is to save one of those embossed tablets and present it at the drug store with the request they want "ten cents more of those." Why do you blame your patients when they quit you? They not only quit, but they divide their "A K's" and "Q B & S's" and other embossed cure-alls with their suffering neighbors while detailing their ailments over the back fence. You have sown the wind, now reap the whirlwind; you have boomed Scott's Emulsion, allowed it to go to your patient with fifty pages of "literature" wrapped around it, till they know just how and when to use it, till it became a household word, and they come no more to you for a prescription. The makers know it, too. They no more care a rap whether the doctors prescribe it or not. They have become millionaires, advertised it on fences and out buildings and in the daily papers, among "youthful indiscretions," "lost manhood" and "female regulators." Can you figure out why your practice is not what it used to be? After you have made the discovery, pass it along to some other fellow who has lost his where—am—I—at. Then before old age overtakes you hunt up your materia medica, your book on therapeutics, where you left off in school twenty or thirty years ago, and learn to prescribe standard preparations that will give you results at less than half the price. Don't try remedies on your patient, something of which you know and more of which you know you don't know, and then expect results. If you are sure your patient needs strychnin give it in 1/60, 1/30 or 1/20 grain doses every three, four or five hours, then you ought to get definite results. If you want to give quinin, give the exact amount your judgment dictates at stated intervals, and you have a right to hope for definite results. Don't give Dad's quinin, bromo-quinin or a similar mess, because you don't know what either of them is, and can't expect any definite results. If you want to give a mixture of quinin, strychnin and digitalin, give a certain amount of each at regular intervals. Don't use instead an unknown mixture which the label says represents the active principles of Peruvian bark, nux vomica and foxglove, because even if the label is truthful you don't know what active principles were selected by the maker or whether any were used at all.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908

I have lectured extensively on this matter and on the object of food adulterations, and the more I study the subject the more I am convinced that I am making no overstatement but am merely touching the high places. My friends from the metropolitan centers may claim these things are only true of country doctors and small towns. No greater error exists. Go into any popular, first-class drug store in New York, Philadelphia, Boston, Chicago, San Francisco, New Orleans or St. Louis, places to which fashionable physicians send their prescriptions, and you will be astonished at the large percentage of prescriptions that contain secret or semisecret, ready-made preparations with meaningless names, the formulas of which are unknown or but partly known to the prescriber. A physician of high standing, a former professor of obstetrics in a state university medical college, wrote a prescription containing haarlem oil, satyria and neurilla. He did not know the component parts of any one of the three items. Another wrote a prescription forming a horrid mess, containing acetanilid, antikamnia, quinin sulphate, sodium salicylate, tincture of the chlorid of iron and yerba santa compound. The patient had an acute attack of influenza with rheumatic pains, and this wise doctor was going after all the sore spots in his patient, so as to be sure to make a hit somewhere. It was a villainous mixture of known and unknown stuff, but the patient had sense enough to refuse to take it. Go into any drug store and notice how the shelves of the prescription department are literally groaning under the weight of the proprietary semisecret remedies, almost to the exclusion of the simple, standard, well-known remedies.

To make this matter concrete, I went into one of our best and most popular pharmacies, and by the courtesy of the proprietor I found the following, to show you merely as an example of hundreds of others. In one group stood listerine, crystalline, pasteurine, glycothymoline, glyco-benzole, formalyptol, thymoline, euthymol, thymoliptine, borolyptol, Wampole's antiseptic solution, therapogen and many more imitations, all of which could be easily supplied at less than half the cost by the Liquor Antisepticus of the U. S. Pharmacopeia. All of these the druggists must have on hand, to satisfy the whims of the different physicians who don't care to take the trouble to inform themselves that all these so-called antiseptics are practically identical, answer the same purpose, and but few of them are any better than a saturated solution of boric acid, worth ten cents a pint; and nearly all of them are semisecret. Another instance. There is uric antagon, whose label says it contains the *active* principles of phytolacca dec., seranoa serrulata, styllingia sylvatica, cimicifuga rac., and aconitum napellus a mere trace, not enough to depress the heart. This is sold you as a uric acid solvent. But you are not told how much of each ingredient it contains, nor which active principles are used. Oh, no; yours only to do as you are told.

Isn't this an insult to an intelligent profession? When the uric antagon man came to my office, I ordered him out and threatened to throw his sample out of the window if he didn't take it away. He did not wait long enough to be told twice. Then there is uriseptin, that professes on its label to cure nephritis, albuminuria, dropsy, enlarged prostate, pyelitis, retention of urine, enuresis, gonorrhea, blenorrhea, and any other sexual or urinary ailment. The label says it contains formaldehyd, lithium, corn silk, couch grass, and 6 per cent. of alcohol. No quantities are given for fear some imitator may tap their gold mine. Any physician, however, that has sense enough to prescribe for a case of chickenpox, can easily supply the quantities and have it put up at a drug store at one-fourth the price the makers ask. Tongaline (Mellier), we are told by the label, contains certain quantities of tonga, cimicifuga, salicylate of soda, colchicum, pilocarpin and 33 per cent. of alcohol. No quantity is given except the alcohol, which the Food and Drugs Act compels them to publish. A simple prescription by an intelligent physician at less than half the cost would answer at well, if not better.

Anasarcin, a tablet sold by a Tennessee firm, and Anedemin, a similar one put out by another firm, are both sold at fabulous prices. They contain sourwood, squills and elder flowers and are easily replaced by a tablet made by any reputable firm at $3 a thousand, or for about what the exploiters sell theirs a hundred. The formula given by the ethical houses for a similar tablet is, extract sourwood leaves, 2 gr.; extract elder flowers, 2 gr., and extract squills ¼ gr., which shows just what you are giving, and also shows the contents to consist of inexpensive material. In my hands they have served an excellent purpose and are a splendid substitute for the secret, robber-price goods, and I know just what I am giving.

You may say to me: Would you not have any ready-made formulas, and thus deprive us of the convenient and often efficient preparations? They are an especially useful lot of preparations to the busy dispensing physician, and some of them are not only difficult but well nigh impossible to make up extemporaneously on short notice, even by the most skilled pharmacists. This is all true, and I am myself a great friend and user and even dispenser of many of them, and recognize their convenience as well as their efficiency. But I buy them of houses that are honorable enough to give me and my patients a square deal by publishing the entire and exact formula, and selling them at prices that are fair and equitable to themselves and to me and my patients. I don't want the label to tell me merely that a certain package contains Early Risers, Little Devils, Sun Cholera Cure, Cascarets (that work while you sleep), Seng, a preparation of ginseng, Sanmetto, said to be composed of true sandalwood and saw palmetto and soothing demulcents; glycozone, whose formula is given as $C_3H_6O_4+C_3H_8O_3$, which, of course, is as clear to you as Missouri River mud. It is as plain as the two isomerics, oil of turpentine and oil of lemon. Both contain the same elements in the same quantities; yet you wouldn't prescribe the one for the other. Why, it is a deliberate insult—an effort to throw scientific sand into your eyes!

Their common atomic formula is $C_{10}H_{16}$, which also is the formula of safran, the pleasant odor of sassafras, and many other pleasant odors of the volatile group. So, you see, whenever these manufacturers offer you only the atomic formula, you can be assured they are "playing horse with you." No self-respecting physician who has the good of his patients at heart will be satisfied with any remedy that offers him a fake formula or only partial one. I now copy at random some of the labels on the bottles in my office. For instance the well-known elixir of bromid compound, or hypnotic compound; each ounce contains chloral hydrate 120 grains, potassium bromid 120 grains, extract of hyoscyamus 1 gr. and extract of cannabis indica 1 gr. This is a convenient, efficient elixir; you know just what and how much you are giving and what to expect. Is'nt this better than prescribing Bromidia, said to contain the same ingredients in unknown quantities, a scant 4 oz. bottle of which is sold for $1.00, while the elixir bromid compound with full formula sells by the best houses for $1.20 a pint. Of course, you are at once told the quality is not so good. In answer to this just ask yourself why it shouldn't be? You will at once come to the conclusion that the first class pharmaceutical houses will put, to say the least, just as fine and pure drugs into their preparations as the Keysall Co., the Antikamnia Co., the Anasarcin Co., the Rio Chemical Co. the Aetna Chemical Co. and the hundred more such people, who don't even give the names of the individuals composing the fanciful firm names behind which they are hiding. Reputable firms put up an elixir of saw-palmetto and santal compound which beats Sanmetto, put up by the Od Chemical Co., to a standstill. Reputable pharmaceutical houses offer a formula like this:

Saw-palmetto berries	120 grains.
Sandalwood	30 grains.
Corn silk	120 grains.

in each ounce of the elixir.

Now you know what this is. Can any one tell what's in Sanmetto which sells for $8.50 a dozen half-pints, while the elixir sells for $5.25 a gallon? What results can you expect when you give an unknown remedy? It is like a man closing his eyes and firing a gun promiscuously into space and then opening his eyes to hunt what he may have hit. Wouldn't it be better if he would hunt his game first, know what kind of a gun he has, know just what it is loaded with, and take careful aim before he pulled the trigger? And a good rifle is better than a scattering shotgun when you want to do precise work.

Then, also, wouldn't single remedies, preferably the alkaloids, and active principles, freed from the dirt and dross with which they are often associated in nature, be more satisfactory than crude galenicals of variable strength? Do you hesitate to answer? The formula for the old Warburg's Tincture, an antiperiodic, contained over 100 ingredients—127, I think, was the full number—of which 90 per cent. could be fully dispensed with. If you want strychnin effect, why prescribe nux vomica? If you want quinin why give the nasty, bulky Peruvian bark? If you want to give morphin or codein, why give opium? And so on, a thousand times could I give you examples only to take up your time. But a hint to the wise is sufficient.

What is the remedy? There is one, and I will tell you. Study your Pharmacopeia, your U. S. Dispensatory, your National Formulary and some modern works on materia medica and therapeutics; renew these every five or ten years. Supplement these by the best authors on practice, pathology and diagnosis, and read a few of the best medical journals — not the advertising pages only; attend your county, state and national medical societies, and you will know more medicine in five years from now than you could get in fifty years by reading proprietary medicine pamphlets and cheap medical journals, whose print isn't worth the paper used in binding.

Do you ever read in your standard books on practice, such as Osler, Flint, Anders, Tyson, Bartholow, Nothnagel, Holt and others just as good, that they recommend such slush as the *Medical Brief* has prescribed for you during the last quarter-century? What would happen to a physician who would read a paper before a decent medical society in which he would extol the virtue of such stuff as anasarcin, ecthol, syrup of figs, castoria, sanmetto, satyria, Dad's specific, exalgine, thermol, antikamnia and Micajah's uterine wafers? What would happen to him? Then why use such things? If it isn't decent to write or talk about them or recommend them, why use them surreptitiously? Can you give yourself such an answer as you would be willing to publish over your signature? I think not. In fact, I know you can't.

Now a word by way of suggestion. You may ask how you can distinguish between the good and the bad proprietary pharmaceuticals. One way is to insist on the full, complete formula. Some houses tell you they will not publish the formula on their labels, but will send it to you on request. That will not do. In the first place, they seldom do it when you ask for it; I have tried them. They usually send you a garbled formula giving only some of the ingredients. Besides, the "patent medicine" people will do the same. They will send you full and complete formula on request; in fact, the Ayer people have succeeded in getting several "snide" medical journals to carry their advertisements in which they challenge the admiration of the unwary by publishing a full formula. But we know their past record. I could give many more hints, but the best rule of all is to pay some attention to these things, and in a short time you will be able to recognize fraudulent proprietaries as quickly as a turkey-buzzard can scent a dead sheep.

Lately a very efficient source of help and instruction has made its appearance which will assist you very materially to distinguish the true from the false, no matter whether it is made in St. Louis or whether made in Germany and recommended by Doctor Herr Geheimrath von Ladislaus Ober-Schaffhausen, or it may be Mr. Updigraff-Jones of Holborn Viaduct, London. This is the laboratory reports of the Council on Pharmacy and Chemistry of the American Medical Association, whose work is recorded every week in THE JOURNAL of the American Medical Association. While some think the findings of the council may not always be final, nor their recommendations unbiased nor unprejudiced, yet it is making some people sit up straight and take notice. Every week there is given the results of examination and analysis and claims put forth by the manufacturers of certain articles such as I have mentioned to you in my paper. Recently they discussed Kutnow's Powder, probilin, the active principles of ergot, Dr. Robert's very ethical (?) hydrocine, the "positive consumption cure," vin mariani, the organic irons and others. Whatever you may think of their conclusions, you can't help acknowledge that you were instructed and interested. This alone will prove a death blow to quackery.

One thing is certain, there is no good reason why proprietary manufacturers of secret and semi-secret medicine shall wax fat at your expense and that of your patients, while some of you can scarcely make a decent living, clothe yourself and wife and children properly, and educate the latter as becomes their station; while farmers, bricklayers, carpenters and street sweepers are laying up money at an expense and outlay simply of muscle.

A learned and exalted profession must ever maintain its self respect in order to command the respect of others. As social factors in the world's progress, as heralds of good tidings of a better life, as scientific exponents of a higher civilization, in stamping out disease, epidemics, pests and contagion, as carriers of the gospel of health and happiness into the remote portions of the earth, as advance agents of the higher creed of humanity, the medical profession stands first and foremost and second to none.

As such we can ill afford to play second fiddle to a lot of nostrum fakers. Let us be worthy of the high place our profession has ever occupied among the people, and what we have not yet attained that we deserve; let us demand it by reason of our usefulness, our conduct with our fellow men and our self respect.

In the language of one of the immortals, let me admonish you—

> "This above all: To thine own self be true;
> And it must follow as the night the day,
> Thou canst not then be false to any man."
>
> —Shakespeare.

1007 Fifth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. SOLLMANN, ANDERS, WILEY AND WAHRER.

PROF. JOSEPH P. REMINGTON, Philadelphia: At no previous meeting of the American Medical Association which I have attended has the subject of the U. S. Pharmacopeia been given so much attention. I was present at the very first meeting of this Section, to which a few representatives of the American Pharmaceutical Association were invited by the American Medical Association. At that time the meeting was very small; sometimes five or six, sometimes I think two were present, the chairman and the secretary. This discussion on the United States Pharmacopeia shows an intense interest in this work. To awaken an interest in the U. S. Pharmacopeia in the past, papers have been read here in the American Medical Association and before medical societies all over the United States, and in the Convention for the Revision of the Pharmacopeia the members of the medical profession were asked and begged to come to the meetings. The fact remains that the members of the medical profession have not cared for the Pharmacopeia in the past. But they are coming now. To many of Dr. Sollmann's suggestions in regard to the method of revising the Pharmacopeia I can say amen. Few pharmacopeias are revised oftener than once in ten years. The French Codex is sadly in need of revision, but they are at work at it now. So far as the time of revision is concerned, the United States is not far behind other nations, but in all foreign countries the pharmacopeias are legal standards, and the U. S. Pharmacopeia was not made a legal standard until the Food and Drugs Act of June 30, 1906, made it such. The Committee of Revision has been approved by the government. My secretary has half a peck of commendatory letters from many sources; some say that the method of revising the U. S. Pharmacopeia is the best that has been devised. It is curious that many Americans want to change the method of revision while Dr. Tyrer, the president of the British Pharmaceutical Conference, says that the United States Pharmacopeia is better than theirs. I think that the majority of the Committee of Revision would vote for a revision once in five years. The Board of Trustees of the Pharmacopeial Convention have already expressed themselves in favor of a more frequent revision. It has also been proposed to revise the Pharmacopeia once in three years; but such a pharmacopeia would be a menace to the makers of all kinds of preparations and would encounter a great deal of opposition because three years is too short a time to test fairly the various preparations. It would certainly cause great confusion in the medical profession. Physicians would no sooner become used to a preparation and learn how to use it than they would find that it was either abandoned by a new Pharmacopeia or its strength changed, and they would have to forget the old and learn the new. The United States Pharmacopeia revised only once in ten years is not known as it should be. It seems to me that the good middle ground of five years would be most satisfactory. It is true that a supplement was issued to the French Codex, the British Pharmacopeia and others. There is a great disadvantage about supplements in the back part of the book, namely, that they are apt to be overlooked. A great many men use the Pharmacopeia as they do a dictionary or encyclopedia, since subjects are arranged alphabetically and the index is ignored. If a revision were made once in five years, however, there would be no need for a supplement.

I was sorry to see in one of our western publications an allusion to the Star Chamber method of conducting the work of the revision of the Pharmacopeia. A work of such magnitude as this involves grave responsibilities. Every effort was made to find the will and the wish of the greatest number. There was no secrecy whatever about the work. The most modern methods were used in order to obtain the opinions of individuals and organizations and to arrange the information when obtained. The whole matter was then thoroughly sifted by the chairmen, the subcommittees and the general committee. It must be remembered that the committee is confronted with an enormous task in deciding between various earnestly advocated preparations and modifications. Laboratory work has been used most largely; the committee and subcommittees have had processes tried repeatedly by many workers and experts. Please remember that the U. S. Pharmacopeia can select only one method as a rule. It is impossible to satisfy all who are interested. A committee should be appointed in whom faith can be reposed and the responsibility should be left to them. Some one recommended that every proposition affecting the Pharmacopeia be submitted to the county medical society of each county in each state. they to consider the subject and to forward their decision to the Committee on Revision. Now how long will it take to issue a Pharmacopeia after hearing from every county society in every state in the union? If that is done the next Pharmacopeia might be issued in 2016. Dr. Sollmann advocated publishing conclusions every four months. Could the Pharmacopeia be issued in three years under those conditions? Is it possible to get out a book in three years when all these propositions are to be laid before the country in advance? But the suggestions and propositions are now in order for the next revision. Let the committee settle them as far as possible. It is not generally known that the U. S. Pharmacopeia is controlled by a Board of Trustees and that the U. S. Pharmacopeial Convention has a charter from the United States. Its officers are permanently charged with the duty of revising and issuing the U. S. Pharmacopeia. A remark was made implying that the assignment of work had been done hastily. Twenty-six members composed the Committee on Revision. It took fully six months of the most careful painstaking effort of Dr. Charles Rice, the former chairman of the Committee of Revision to arrange and assign work to the members of the fifteen subcommittees. Then, again, delay was caused by the death of some of the members and consequent reorganization. The idea of placing more dependence on the chairmen of the subcommittees is certainly an excellent one. No doubt there will have to be radical changes in the work of the Committee on Revision. If revision is made every five years it must necessarily mean a change in the construction of this committee. The plan on which the work is conducted is one devised by Dr. Rice a number of years ago. It required approximately 2,260,000 words used in general committee official correspondence alone. But the chairmen of the subcommittee as representatives should be given more influence in the general committee than other members because of their greater special knowledge. The Committee on Therapeutics was charged with the duty of reporting on the admission or exclusion of drugs. Exclusion is as important as admission. When a preparation is expunged the committee is going to hear in no uncertain tone from the men who have used it for years and years because the Pharmacopeia is for use in Georgia or California, as well as in Chicago or Washington. The whole country must be considered.

Let us welcome every suggestion that can be made for the improvement of the Pharmacopeia. The Committee on Revision and the Board of Trustees have not and never had the remotest intention to slight or ignore the physicians of this country in the work of revision. In the constitution and by-laws of the U. S. Pharmacopeial Convention ample representation is given to the medical profession. I know that on May 2, 1910, when the next Pharmacopeial Convention meets in Washington the members of the American medical profession are going to be there and we are not going to be troubled with lack of interest hereafter.

Mr. M. I. Wilbert, Philadelphia: I believe that the pharmacists of this country are to be congratulated on the fact that the members of the medical profession have again awakened to their duty in relation to the Pharmacopeia. If medical practitioners will but study the history of the Pharmacopeia they will take an even more active interest than is present indicated. While it appears that there is but one pharmacopeia which has been revised in much shorter time than our own, there are a number of reasons why other pharmacopeias have been delayed. The German Pharmacopeia was issued within one year of the time the revision was authorized, because the revision was made before the authorization to publish took place. Germany has a standing revision committee which is constantly at work. At the present time the German Pharmacopeia is being actively discussed, and it is probable that the next revision will be issued within six months of the time the revision is authorized. The revision of the Swiss Pharmacopeia, it is true, took five years. This was due, however, to the entire reorganization of the methods of revision. The Swiss Pharmacopeia was originally a book devised and revised by the Pharmaceutical Society of Switzerland. The present pharmacopeia is the first that has been legalized as the standard and also the first in the revision of which medical men took part. The Swiss have adopted a method that appears commendable and one that is well worthy of being followed by our own Pharmacopeial revision committee. In addition to possible corrections, provisions have been made for a complete revision in a very short time. The method of revision outlined by Dr. Sollmann appears to be somewhat complicated, but, on closer study, might prove itself to be comparatively simple. The revision committee of the Swiss Pharmacopeia depends on nine chairmen of subcommittees. These nine chairmen are responsible for the work, each man being individually responsible for the work in his department. The chairman of a subcommittee apportions the work out to members of his own choosing and they refer it to men who are supposed to work with them. The completed work is then referred to the chairman of the subcommittee and the chairman of the subcommittee subsequently refers it to the committee on editors. There are, of course, many things that some of us do not like in our own Pharmacopeia and many things that others do not like in foreign pharmacopeias, but we can not expect to get a pharmacopeia that will please all of us. The one thing to do is to get a pharmacopeia which will please most of us. I believe that the U. S. Pharmacopeia of 1910 will be the best that has ever been published in this or in any other country.

Dr. Robert A. Hatcher, New York: A year ago a resolution was offered, asking that a committee on the Pharmacopeia be appointed from the American Medical Association. The duties of the committee were outlined in a paper presented by Dr. Osborne. I was appointed a member of that committee, and while I recognized a good many of the shortcomings of the Pharmacopeia, I had rather a vague idea of the way to remedy some of these evils. I thank Dr. Sollmann, not for myself alone, but for the other members of the committee, for pointing out ways to approach the solution of some of these difficulties. Dr. Sollmann spoke of cooperation of medical bodies if they were assured that cooperation was desired. That assurance has been given. The chairman of the Committee on Revision of the Pharmacopeia has shown unequivocally how glad the committee is to receive suggestions. If each man in this audience becomes a committee of one to arouse a general interest in the county and state societies much good will result. These separate county and state societies need not send individual reports, but they can express their views through delegates in the coming convention. Dr. Sollmann spoke of unscientific preparations and preparations not found in the Pharmacopeia. The two terms should be synonymous; the Pharmacopeia must be made to contain every thing which rightfully should be prescribed. If the medical profession expresses itself intelligibly the Pharmacopeia will represent everything that is necessary. I believe that if we as individuals singly and collectively are recreant to our duty toward the Pharmacopeia, the government will cease to sanction it. I believe that the government which sanctions that work will take it over into its own charge.

I think that Dr. Sollmann's suggestion of frequent partial revisions or supplements to the Pharmacopeia is entirely feasible. The work of the Council has shown that it is not at all difficult to make constant additions to "New and Nonofficial Remedies," and that little work has gone through three editions. There is no reason why a substance should wait more than one week after it is subjected to crucial tests and it is decided that it shall be made official; it should be made official that very day, not in a year. Frequent revision does not necessitate frequent revision of everything in the Pharmacopeia. There is no reason why phenacetin should be kept out four or five years for fear a change would be made in the method of manufacturing fluidextracts and preparations in general.

Dr. Reid Hunt, Washington, D. C.: The committee on the Pharmacopeia to which Dr. Hatcher has referred has met and outlined a course of action. I hope that this committee will become the clearing-house for the views of physicians in regard to the Pharmacopeia. We shall be glad to have suggestions from anybody who will care to make them as to the physician's part in the Pharmacopeia.

Prof. W. A. Puckner, Chicago: The work connected with the revision of the Pharmacopeia is going to be much less than heretofore. More scientific work is being done today. At the last revision I was frequently consulted in regard to certain lines of work; the committee with which I was associated had to do a great deal of experimental work. Now a great deal of work of this kind is being done. The work of the Council on Pharmacy and Chemistry no doubt will be of the greatest value in the revision of the Pharmacopeia. The Council is testing the new drugs and trying to establish standards for them so that if they are found worthy to be admitted to the Pharmacopeia the standards will have been worked out. The Council has been attempting to establish uniform standards for certain classes of preparations. It urges manufacturers to provide, at the same time that they introduce a new drug, a method of demonstrating its purity and strength. In this way I am sure that the next revision of the Pharmacopeia will be much simpler and it will take a much shorter time to get it out because of the preparatory work which is being done throughout the United States at this time.

Dr. C. S. N. Hallberg, Chicago, Ill.: As I have said before, the United States Pharmacopeia approaches more nearly the status of an international pharmacopeia than any other. If we were to make a synthesized combination of the leading pharmacopeias of the world we should then probably have a pharmacopeia that would comprise most of the articles prescribed in this vast country. Yet it would have to go beyond this to provide for the profession in our insular possessions and would possibly require a Spanish edition—which, by the way, has been taken care of already by the trustees. I believe that the Spanish translation of the U. S. Pharmacopeia is now ready for distribution. But the great question has always been, What shall go into the pharmacopeia and what shall be placed under the ban? At a preliminary meeting, for example, some one objected to the inclusion of Emulsion asafetidæ on the ground that it was an obsolete remedy; but on the testimony of a Philadelphia physician, who found it of value as a rectal enema, it had to be kept in the Pharmacopeia. The trustees of the Pharmacopeia have arranged for the publication of a sixty-four-page booklet comprising the titles of the Pharmacopeia, the National Formulary, the "New and Nonofficial Remedies" and some unofficial titles, representing almost 2,000 titles. It is intended to circulate this all over the United States and have pharmacists check off from their prescription files 1,000 consecutive prescriptions. If we get 1,000 of these books filled we shall have statistics on what has been prescribed throughout the United States on 1,000,000 prescriptions by the time the next committee is formed two years from now. Then for the first time the Committee on Revision will really know just what is being used in this country. As to whether we should put in what is being used or what the leading medical authorities think ought to go in, that is another proposition. The U. S. Pharmacopeia, I think, should contain every reasonable medicine that is being used extensively by the medical profession. I believe that it is not the function of the committee to say whether or not certain popular pharmaceutical compounds, such as the compound syrup of sarsaparilla and camphorated tincture of opium, are inert or have no therapeutic virtue. I believe that the U. S. Pharmacopeia is fully equal, if not superior, to any pharmacopeia of the world. An unfortunate delay in the getting out of the last pharmacopeia occurred chiefly because we had to enter on a new line—the introduction of the serums.

Dr. Bernard Fantus, Chicago, Ill.: The Pharmacopeia, as now issued, is eminently adapted for the guidance of the pharmacist, but of little use to the practicing physician. It seems to me, however, that a "Physicians' Commentary on the Pharmacopeia" is something that would be eminently desirable. An authoritative book might be issued by some representative body, such as the American Medical Association, in which the physician could find the practical information which he needs in prescribing drugs. If, for instance, in describing the taste and odor, the best disguises for these were suggested; if solubilities and incompatibilities were discussed in detail; if the best methods of administration were given, as well as full information on dosage, frequency of repetition of dose, etc., we should have a book that every physician would want and study. I hope that some means will be found to have such a book issued by the American Medical Association before very long. An attempt in that direction has been made in the "Physicians' Manual of the U. S. P. and N. F." This little book is excellent as a beginning; but, I believe, it does not give quite enough information.

I wish to defend the teachers of materia medica and therapeutics. They are usually among the least influential members of the faculty. Their courses are generally crowded down into the freshman and sophomore years of the medical curriculum, and given the minimum of hours required by the state boards, which, as has been my experience as a teacher in this branch, is less than one-half of what is absolutely necessary in order to do creditable work. It has cost me a great deal of effort to get more adequate recognition for the branch in the school with which I am connected. I hope that Dr. McCormack's suggestion of this morning will be acted on, and that the state boards will recognize the importance of the teaching of this branch. Joint meetings of physicians and pharmacists ought to be held frequently, at which important drugs might be discussed, both from the standpoint of the physician and from that of the pharmacist.

Dr. M. G. Motter, Washington, D. C.: The next Pharmacopeial Convention is now not two years off. Before the American Medical Association shall again assemble the call for the appointment of delegates to the convention of 1910 should have gone forth, and, as a member of the committee on credentials, I wish to emphasize what has been said about the utter indifference of the great majority of the medical profession to the Pharmacopeia, both as to attendance at the convention of 1900 and the fact that the proceedings of that convention show reports from not more than a half dozen medical organizations in this country with reference to the subject. It seems to me that imitations of such heterogeneous mixtures as are marketed by certain trade combinations should scarcely have place in the Pharmacopeia of 1910. I should like to see every committee on the Pharmacopeia take up this question.

Dr. Alexander S. von Mansfelde, Ashland, Neb.: It is an old saying that everybody's business is nobody's business. I have had the honor of acting as the presiding officer of the House of Delegates of the Nebraska State Medical Association since its commencement, and I have not seen any communication from the Committee on the Revision of the Pharmacopeia. I do not need to assure you that if anything officially had come to us it would have been taken care of. I mean to say that there ought to be some step taken by this Pharmacopeial Convention, besides notices in the newspapers and journals. Official letters should go to the state associations to call for the assistance required. So far as Nebraska is concerned, it will be given.

Dr. Torald Sollmann, Cleveland, Ohio: It is a great satisfaction to me to obtain the ideas of the chairman of the revision committee. I feel that a great many points on which we are at odds are matters of misunderstanding. For instance, Professor Remington misunderstood me when he thought I said the pharmacists had too large a representation. Not at all. I think that the Committee on Revision proper should consist almost entirely of pharmacists. Another misunderstanding was apparent in Professor Remington's statement that the revision committee would be indefinitely delayed if it should write to the county medical societies and give them opportunity for reply. It was not in my plan to wait indefinitely, but only to give reasonable opportunity and encouragement. I do not see why this should delay revision in the slightest degree. As to the frequency of revision, I agree that as soon as it becomes plain that a thing should go into the Pharmacopeia, there should be no delay. I think that five years is too long to wait. As to the publication of supplements, reference to my paper will show that I did not intend to have these placed in the back of the book where they would not be seen. Professor Remington explains that most of the power as to admission was left to the therapeutical members. This is very well, but it is accidental, as there is no definite rule. I believe that the admission committee should be elected directly, independently, but to work in association with the Committee on Revision as I have outlined. As to subcommittees, Professor Remington explained that six months was occupied in assigning each man to his place; that the method has been a most careful one. It is quite conceivable, however, that a suitable man for each position would not be available in the revision committee, when this is elected at large by a general convention which is not instructed as to which place each member is to occupy. Direct election would again seem a simpler and surer method.

Prof. J. P. Remington, Philadelphia: We have the right to call on any expert in any branch. All that the committee has to do is to ask for such a man and the request is put to vote. For instance, we had an expert from Montclair, N. J., an authority on volatile oil. In nearly every subcommittee experts were employed and the men we have asked to help have never refused.

Dr. C. F. Wahrer, Fort Madison, Iowa: My paper contained much censure. I wish, therefore, to say that the work of the *Council on Pharmacy and Chemistry*, which is publishing its deliberations weekly in The Journal, is one of the best means that has been put forward thus far in order to cure the evils I have mentioned. One man may lead a horse to water, but 20,000 can not make him drink. If pharmacopeias are revised every five or ten years, or oftener, the very people who should read them will not. What can we do with them? The American Medical Association can wield a great influence; there are 32,000 members now, I am told. They will finally overcome these miserable trade journals, some of which since they became rich have become good. Let's keep up a constant warfare. It means a campaign of education, and I trust we shall keep at it until the body politic of medicine, which is now like an evil sore, is cleansed.

A FURTHER CONTRIBUTION TO THE HISTOPATHOLOGY OF PARAFFIN PROSTHESIS.*

M. L. HEIDINGSFELD, M.D.
Dermatologist to the Cincinnati Hospital.
CINCINNATI, OHIO.

In September, 1906, I presented to the ninth congress of the Deutsche Dermatologische Gesellschaft a report of the histopathologic changes which paraffin underwent in two cases in which prosthesis had been performed by two self-styled dermatologists or "beauty doctors" for cosmetic results. I report herewith some further clinical and pathologic observations in one of my earliest prosthetic cases:

CASE REPORT.

History.—Miss H. S., aged 11, presented herself in May, 1904 for cosmetic correction of a number of facial cicatrices resulting from chickenpox, incurred when she was 8 years of age. From May 16 to June 17, 1904, twenty cicatrices of varying size and depth, situated over various portions of the face, were carefully obliterated with hypodermically-placed paraffin (melting point 52 C.), under cocain anesthesia. The paraffin was injected in a fluid condition by means of a powerful metallic syringe, which, together with its contents, was immersed in hot water immediately prior to each injection made. The paraffin employed was specified to be of one definite melting point, but there is reason to believe that it was composed of a mixture of paraffin of high melting point and oil of vaselin. The immediate results obtained in the case were excellent; the injections were made without incident, and with relatively little inflammatory reaction. When the patient presented herself on October 5, 1907, after an absence of over three years, the cicatrices were again evident almost to their former degree of depth and outline, and much more disfiguring in their character, for the reason that all of them were considerably pigmented, and surrounded with a faint zone of mild inflammatory reaction. The disfigurement was more pronounced than at the time when prosthesis was first attempted, and of such a character that an extirpation of some of the larger and more prominently situated lesions seemed imperative. One of these lesions was removed October 12, 1907, and forms the basis of the subsequent report, which conforms in nearly all particulars to those observed in the two cases previously reported and to cases of the same general character thus far recorded in the literature.

Histologic Examination.—The epidermis is normal except for a slight proliferative activity confined to small areas of the lowest interpapillary germinal cells of rete mucosa. The same degree of activity is noted in the epithelial cells of the hair follicles and sweat glands, whose orifices are moderately distended with keratotic exudate. The sebaceous glands are hypertrophied and envelop their respective hair follicles on all sides. The sudoriferous glands show a moderate cystic dilatation, and endothelial proliferation. The cutis shows no pathologic change except a moderate degree of vascular exudate centered about the smaller capillaries. The prosthetic area is encapsulated with a wall of connective tissue, and is the site of numerous cavernous spaces, which give the specimen under low power a honey-comb appearance or that of a well aërated piece of Swiss cheese (Fig. 1). The spaces are the site of paraffin in unchanged or slightly changed form, removed by the alcohol and xylol in the process of hardening and clarification. Many of the smaller spaces are only partially obliterated and contain flattened degenerated cells and leucocytes. Most of the spaces are surrounded with a dense wall of infiltrating leucocytes and loose connective tissue, which imparts to the specimen the appearance of a granuloma not unlike that of tuberculosis before caseation manifests itself.

The presence of numerous giant cells intensifies the resemblance to tuberculosis. Under higher power the prosthetic area is seen to be made up of cellular elements, which are grouped in alveolar form and surrounded by a mesh-work of loose areolar, inflammatorily infiltrated connective tissue. The alveoli contain a large number of cells and degenerated cellular products and an extensive infiltration of leucocytes. The cavernous spaces are surrounded with a thick infiltrating wall of leucocytes. The smaller partially occluded cavities are observed under high power to contain masses of flattened degenerated cells, with here and there an occasional leucocyte. The distinguishing and characteristic pathologic changes are the Swiss-cheese-like general appearance under the low powers of the microscope, the alveolar-like distribution of the inflammatory products and the abundance of giant cells.

THE PATHOLOGIC PROCESS.

The pathologic process which a disintegration and removal of the paraffin by leucocytic action is effected as follows: The paraffin when injected is distributed in strands along the lymph spaces, and between cellular structures, and here and there *en masse* by the rupture of tissues and their forcible distension. Its presence as a foreign body excites a reactionary inflammation sufficient to wall it off from the surrounding tissues and secures its encapsulation with newly-formed fibroconnective tissue. The leucocytosis is then directed against the paraffin proper, beginning with a peripheral invasion and disintegration. The new army of invasion yields to degenerative changes, in the form of a flattening of the cells, with loss of nucleus, and general staining properties. This army of degenerated cell invasion is succeeded by a second army which undergoes a less complete form of degeneration, with the nuclei preserved, thereby forming masses of giant cells. These in turn are invaded by a third army, which has for its ultimate object a complete fibrosis. All these changes can be readily traced in their successive steps, the larger cavities retaining in their central zones the paraffin in its unchanged original form, the next smaller caliber cavities show the first step in the pathologic change, the next. the second, and smallest alveolar spaces. corresponding to the thinnest strands of injected paraffin, show evidence of fibrosis in its most complete form.

---

* Read in the Section on Cutaneous Medicine and Surgery of the American Medical Association, at the Fifty-ninth Annual Session, held in Chicago, June, 1908.

Pigmentation following paraffin prosthesis is unusual, and this is the first instance which I have encountered in my personal experience. As far as I have been able to examine, the literature reveals but a single instance; Pigand[1] reports a case of discoloration of the skin, with ulceration and fistula following an injection of soft paraffin into the breast. No further light was shed on the nature of the pigmentation in my case by the histologic examination; examination of unstained sections revealed a slightly abnormal amount of pigment in the lower layers of the rete mucosa, and the number of pigment carrier cells in the papillary layer of the cutis was slightly in excess of the apparent normal. No pigment could be observed in the proximate area of the prosthesis. The patient was a pronounced blonde in type and showed no other pigmentation tendencies.

The unstable character of the prosthesis in its clinical aspects does not differ materially in this case from that in others in my personal experience, in which the correction of saddle-nose and cicatricial deformities were more or less temporary in character. Sehrt,[2] among many others, has noted the non-permanent character of these injections, whether soft or hard paraffin was used, and reports a prosthesis in the cheeks which became transformed to connective tissue and invaded with giant cells and inflammatory exudate.

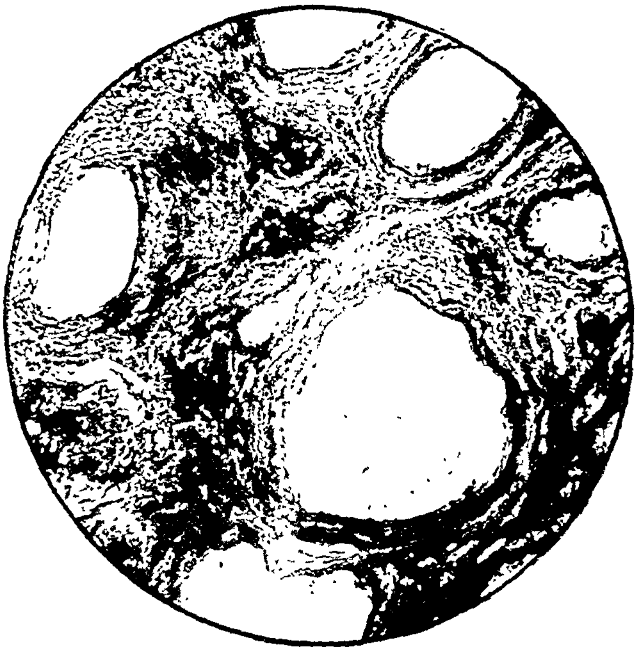

Fig. 1.—Paraffin prosthesis in a case in which the pits from chickenpox were obliterated four years prior to the extirpation which was made necessary on account of pigmentation and recurrence of the cicatrization. The large cavernous spaces are the site of paraffin in unchanged form and undergoing an early stage of degenerated inflammatory infiltration and are surrounded with newly formed fibroconnective tissue. Winkel, objective 3, ocular 2.

Many of the reports, particularly the earlier ones, on the histopathology of paraffin prosthesis are misleading and have been given various interpretations, in spite of the fact that they possess more or less common and uniform characteristics. The earliest investigations have dealt chiefly with the liquid paraffin and oil of vaselin, which were injected into the buttocks as the menstrua for mercurial injections. Allgeyer[3] and Wolters[4] observed cavernous spaces in these cases and believed them to be absorbed bundles of chemically destroyed muscular tissue. These spaces have been regularly recognized and variously interpreted, and rarely credited with being the site of unchanged paraffin. Many investigators even to the present day are oblivious of the fact, or at least their technic fails to indicate otherwise, that the paraffin in the tissues is necessarily removed by alcohol in the process of hardening the tissues, and by xylol in the process of clarification of the specimen, and that its microscopic recognition is only possible in frozen sections, stained with aqueous solutions and mounted in glycerin. Sakurane[5] in a recent careful and painstaking research, which even included the chemical determination of the presence of paraffin, interpreted the large spaces to be the result of the inflammatory reaction called forth by the mercurialized paraffin, and credited as paraffin a number of small round yellowish-red slightly refractory bodies (cell degenerations?), which he observed here and there in the cavities and surrounding tissues.

DANGER OF EMBOLISM.

One of the greatest dangers and most serious objection to paraffin prosthesis is that of embolism. It has occurred for the most part in cases in which liquid paraffin and oil of vaselin have been employed as the menstrua for mercurial injections. Hemiplegia and death have resulted in cases in which olive oil was injected subcutaneously for sustaining life in a case of stricture of the esophagus, and embolic foci found in all the internal organs and viscera. Amaurosis following paraffin prosthesis has been reported by a comparatively large number of writers, but almost invariably where paraffin of low melting point, or a mixture of low and high melting points, was employed. Eckstein's[6] contention that paraffin with 52 + C. will not be followed by blindness still remains to be proved. In this connection I wish to report an additional case in the practice of one of my Cincinnati confrères:

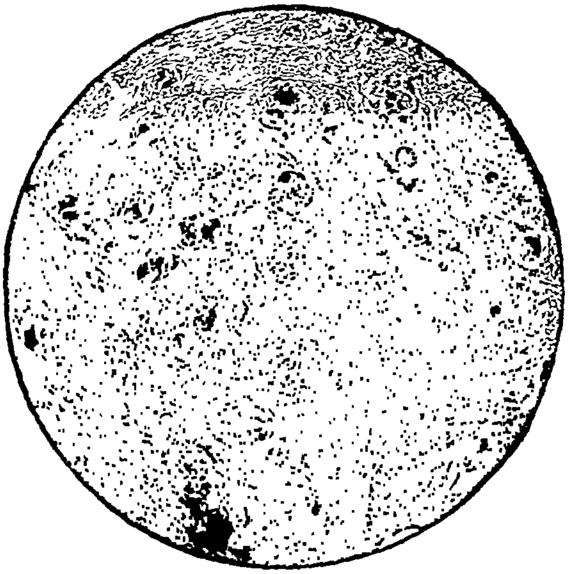

Fig. 2.—Very small prosthetic areas infiltrated with inflammatory exudate and surrounded with newly formed fibroconnective tissue, degenerated leucocytes and gland cells. General appearance, that of a granuloma, resembling an early stage of tuberculosis of the skin. Winkel, objective 1, ocular 1.

CASE REPORT.

History.—A. S., male, aged 21, was injected June 13, July 5 and 26 and August 13, 1907, *for saddle nose deformity*, with paraffin of 43 C. melting point. Paraffin of one definite melting point was specified, but in reality a mixture of hard paraffin and oil *of* vaselin was *employed*. The first three injections *caused* little pain and inflammatory reaction; the last one was made under considerable pressure and was quite painful. At the close of the operation, vision suddenly disappeared from right eye.

Ophthalmoscopic Examination.—The following is the report of the ophthalmoscopic examination by Dr. Jesse Wyler, made August 24, 1907: Right eye stands in slight divergence. Quantitative vision only. Deep blood vessels, remains of a parenchymatous keratitis, seen in cornea with a loup. Pupils react to light and accommodation capsule of lens shows thickened areas, forming opacities of considerable size. Vitreous is *clear. Papilla* markedly white; *slight* crescent outward. Borders are hazy and connective *tissue on the blood* vessels. Small temporal crescent. Veins somewhat larger than normal. *Arteries* normal. Macular region is *free. Diagnosis:* Atrophia nervi optici *secundaria. Patient states* that both eyes went blind ten years ago, but came around all right.

Cases of this character are too frequent to require any special comment, and they continue to occur in spite of the elements of *danger* attendant on the use of paraffin in its various forms and methods of *application*, as constantly depicted by a host of observers and investigators. It has been conceded for years that paraffin workers are strongly predisposed to keratoses, precancerous ulcerations and epitheliomata, yet relatively few operators have manifested a reluctance to deposit paraffin deeply in the tissues, where its subsequent removal becomes definitely precluded and its dangers correspondingly more grave. Davis in a protest against the use of paraffin about eyes, has called attention that its mere deposition in *the capsule of* Tenon following enucleation has been followed by sympathetic involvement of the remaining *normal* eye.

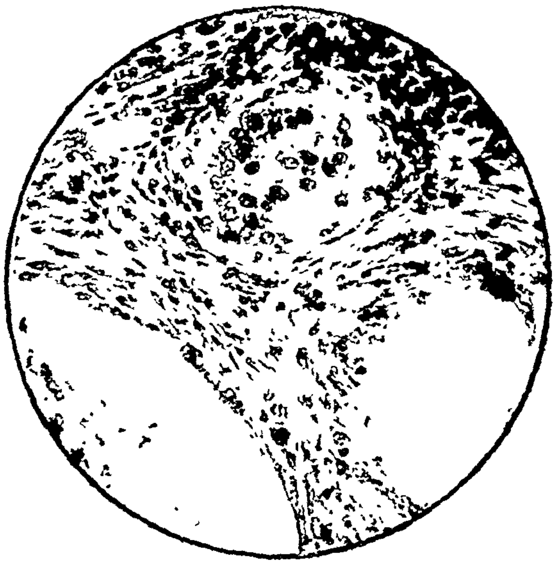

Fig. 3.—Two prosthetic areas containing paraffin in unchanged *form and a third*, the site of a large Langhan giant cell. Winkel, *objective* 4 A, *ocular* 2.

Of considerable interest in this connection are the recent experiments of Emil Beck[7] with injections of bismuth in paraffin for the successful obliteration of fistulous tracts; the excellent clinical achievements of the author in the immediate results will doubtless prompt its further use in hundreds of cases without serious consideration or regard for the ultimate rôle which paraffin will play in these cases. *If the paraffin is* to act merely as bridge or trellis work for the formation of obliterating granulation and connective tissue, as the author indicates, the injection *of sterile* agar-agar, under careful aseptic precautions, in accordance with the interesting and instructive experiments of Kramer,[8] is probably equally preferable and possibly a more *innocuous* substitute for paraffin.

There is one point in the question of paraffin prosthesis *which* requires *further elucidation*, and that is Eckstein's[9] contention that paraffin of *high melting* point remains stable and unchanged when deposited in the tissues. If this is the case, and it *can further* be shown that it also exerts no pathologic influence on the surrounding tissues, prosthetic paraffin may *find* a valued place for itself in therapy of the future. The consensus of present opinion is against this view. My personal observations *and* investigations do not permit an expression on this point, for the reason that I have not thus far been able to exercise a perfect control over the source of *my* paraffin. I have reason to believe that in cases in which I have specified hard paraffin with one definite high melting point I have been supplied with a mixture of hard and soft paraffin. I feel assured that in *these cases* the *hard paraffin* has *disappeared* with the soft paraffin through the agency of phagocytosis, as maintained in my former contribution on the subject; but I am not in a position to state whether or not this would also *have* been consummated without the agency of soft paraffin or liquid albolene.

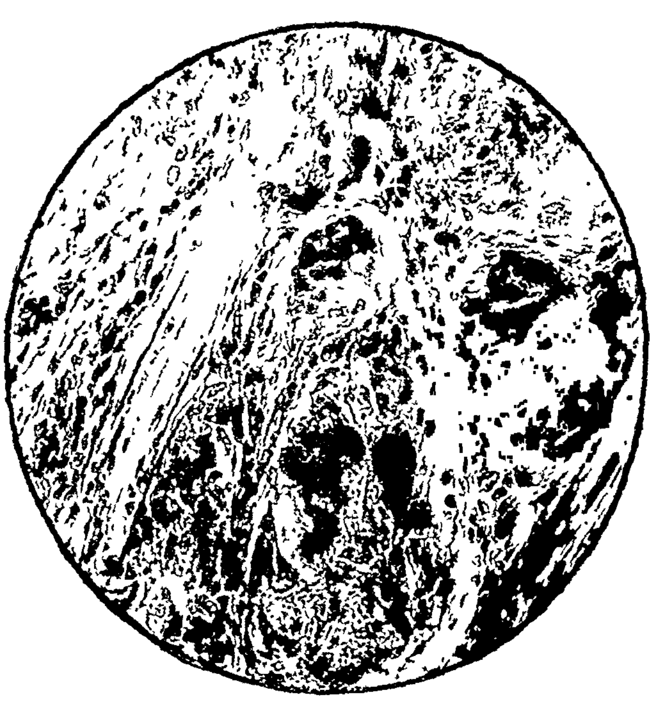

Fig. 4.—Giant cells forming the site of a prosthetic area and invaded by leucocytes. The whole area is undergoing a diffused fibrosis, which is the goal in *paraffin* prosthesis. Winkel, objective 4 A, ocular 2.

From our present state of clinical and histologic knowledge, paraffin when injected into the tissues, *is attended with the considerable danger* of embolism and amaurosis. The paraffin is *promptly* removed by phagocytosis, becomes replaced with fibroconnective tissue, and excites no small degree of local *inflammatory* reaction. Its *presence* is an irritant and foreign to the tissues in which it is *placed*. It may cause pigmentary as well as mechanical disfigurement. It often stimulates surrounding structures to epithelial proliferation and adenomatous change. Its presence excites successive invasions and degenerations of phagocytes and leucocytes, which, with the intermediate formation of giant cells and connective tissue, impart a characteristic pathology, in which the various foci of paraffin become surrounded with a granulomatous structure not histologically unlike that of an early stage of tuberculosis (Fig. 2); later they become surrounded with a wall of dense fibroconnective tissue. The removal of the central portions of the unchanged or slightly changed paraffin (Fig. 3) with alcohol and xylol imparts to the pathology a characteristic Swiss cheese-like appearance. Complete fibrosis (Fig. 4) is the final goal.

THE RELATION OF THE CHARACTER OF THE SYPHILITIC INITIAL LESION TO THE SECONDARY CONSTITUTIONAL PERIOD.*

A. RAVOGLI, M.D.
CINCINNATI.

From common clinical experience amongst syphilitic patients it has been observed that some who had been affected with the typical Hunterian chancre followed by indurated bubo have developed constitutional syphilis much later and milder in character than others who had been affected with small initial papules. The assertion of Marston, Love, Paget, Hutchinson and others, that the more extensive the initial sclerosis, the more severe and stubborn the secondary symptoms, finds no confirmation in my observations. On the contrary, I agree with the observations of E. B. Bronson,[1] that in malignant forms of syphilis the symptoms are much more precocious, the period of incubation is shortened and the constitutional manifestations are hastened. This fact, which not long ago seemed paradoxical, finds to-day an easy explanation in the power of the animal organism to produce elements which oppose the invading pathogenic germs. These beneficial factors are known as antibodies or antigens, and are produced in the blood under favorable circumstances and possess the power to dissolve injurious substances by hemolysis.

The result of the contact of an extract of bacteria with the antibodies in a living organism is immunization. This, although it explained the action in infectious diseases produced by bacilli and cocci, yet did not explain the other infectious diseases, the causative agent of which had been not yet found. The factor causing syphilis has only recently been found and so far has not yet been cultivated. It can not be digested in physiologic salt solution in order to show its antigen. Wassermann, however, came to the conclusion that in the organs in which a large number of spirochetes are found there must be found antigens. The livers of fetuses which have died of hereditary syphilis have been used to obtain the extract, which, in itself, is already capable of producing hemolysis. The serum of syphilitics also has antigens and is capable of clumping so that the union of both shows a single strong action. From these experiments Hoene[2] formulated his serum diagnosis of syphilis. In fact, he was able to establish the fact that in from 60 to 90 per cent. of all syphilitics who have clinical manifestations of syphilis the serum clearly shows antibodies and is capable of producing agglutination. If the serum of a healthy man is used no agglutination results. These experiments so far have no positive results and no practical application, but one thing is true, that in the organism of syphilitics, as a result of metabolism, products are formed which have much more intensive action than is the case in normal organisms. In the serum of syphilitics products are present which are not found in normal serum. To the lack of formation of antibodies by the organism is due the ravages of malignant syphilis. In such cases the spirochetes are left unimpeded and proceed to invade the whole system.

The hardening of the chancre is due to the effort of the organism to agglutinate the spirochetes so they may remain there encapsulated and finally be disposed of. Consequently the greater the reaction the more effect to impede the progress of the new dwellers in the organism. The idea that syphilitic virus constantly follows the lines of lymphatics to invade the organism is no longer tenable, because there are many cases in which the infection takes place quickly and can be traced to the spreading of the virus through the blood vessels.

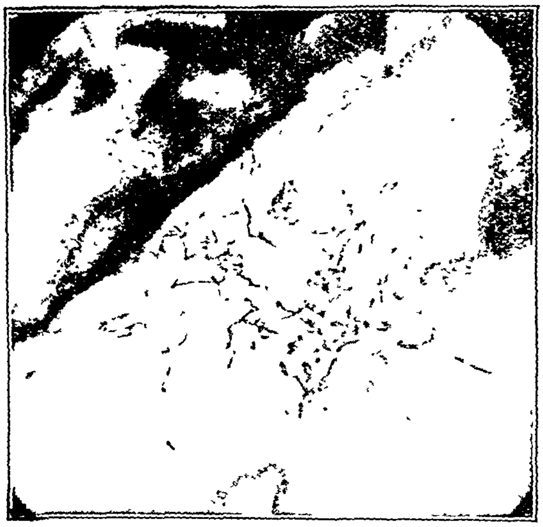

Fig. 1.—Spirochetes in a chancre (1/12 inch oil immersion).

In a series of cases in which the hard chancre was of a severe nature, accompanied with edema, and in which paraphimosis had occurred to necessitate circumcision for the purpose of relieving the pressure and saving the glans from gangrene, the secondary eruption has appeared as late as two and three months. In some cases I have doubted the correctness of the diagnosis of hard chancre for the reason that secondary symptoms did not show up and no constitutional treatment was given.

A strong and otherwise healthy young man was affected with a hard chancre of a very severe type, and in order to save the glans it was necessary to remove the swollen prepuce. The wound healed up slowly but perfectly. The patient had splendid health after that and, being carefully watched, never showed luetic symptoms. The inguinal glands remained slightly enlarged. One year and a half afterwards he complained of a hard and painful node in the left breast. It was a clear case of syphilitic mastitis, which easily yielded to the application of mercurial ointment. Constitutional treatment was administered and he is still being treated.

[1] Primary Syphilis, Morrow, System of Genitourinary Diseases, 1893.

[2] Hoene, Fritz: Die Serum Diagnose der Syphilis, Dermat. Ztschr., 1908, xv, 113.

Another young man, of athletic build and in splendid health, had two hard chancres, one on the urethral meatus and another in the sulcobalano preputiale. Inflammatory symptoms had set in and in trying to bring the prepuce back he could not replace it. He came with the penis greatly swollen, edematous, twisted, the gland bluish in color. There was no time to lose; the prepuce was opened and circumcision performed, a great deal of the chancre being removed. The wound healed up by second intention. The patient, after being relieved of the strangulation of the glans, has always felt well, and shows no sign of constitutional symptoms of lues. Only three months afterwards he showed a mild eruption of roseola, with some erythema of the pharyngeal ring. Lately he had a marked eruption of mucous patches on the tonsils and base of the tongue. Under the treatment with injections of the gray oil he is doing well. Since he was operated on he has never lost one day from his occupation.

Another young man, 26 years old, of good physique and apparently in good health, came to be treated for a little sore on the penis, which he considered of a very trifling nature. Only a day or two before he had noticed three little sores of the sizes of a pin-head close together on the right side of the frenum.

His last exposure dated about two weeks before. The sores were somewhat too deep to be taken for excoriations from herpes, neither did they have the character of the chancroid, and yet they did not show induration.

They were cauterized with 3 per cent. solution of nitrate of mercury, which seemed to have helped a great deal; the patient continued his treatment by bathing the sores with a 1 to 1000 solution of bichlorid of mercury and by applying calomel powder locally.

In a short time the sores had healed up but one somewhat extended, the surface had taken on a bluish-brown color and under the finger a slight, scarcely perceptible, hardening could be noticed. The lymphatic glands did not show any induration or enlargement. The blood vessels around the fossa crurogenitalis showed a net of bluish-red streaks extending to the internal surface of both thighs. This peculiar condition was the result of an angitis with some effusion of the coloring matter of the blood. At the same time the patient began to show signs of anemia, lost his appetite, could no longer attend to his occupation. No more than twenty days from the appearance of the chancres large patches of roseola covered the chest, the abdomen, the arms and the thighs. The patches of roseola in the beginning looked more like wheals of urticaria, from the size of a dime to that of half a dollar, somewhat elevated above the level of the skin The patient was running down considerably in his general nutrition.

Roseola at present has nearly disappeared, leaving only some pigmented spots. The mouth is now the part mostly affected; the tongue, mucous membrane of the cheeks, and tonsils are covered with deep ulcerated patches which render difficult the mastication and prevent swallowing. His present condition is rather bad and shows that a quick and severe case of syphilis has followed an initial lesion which was of a mild and trifling character.

It appears clear that the enlargement and swelling of the lymph glands is due to their action in opposing the invasion of the spirochetes. In the cases in which the glands are very little or not at all involved, syphilis usually takes a severe course.

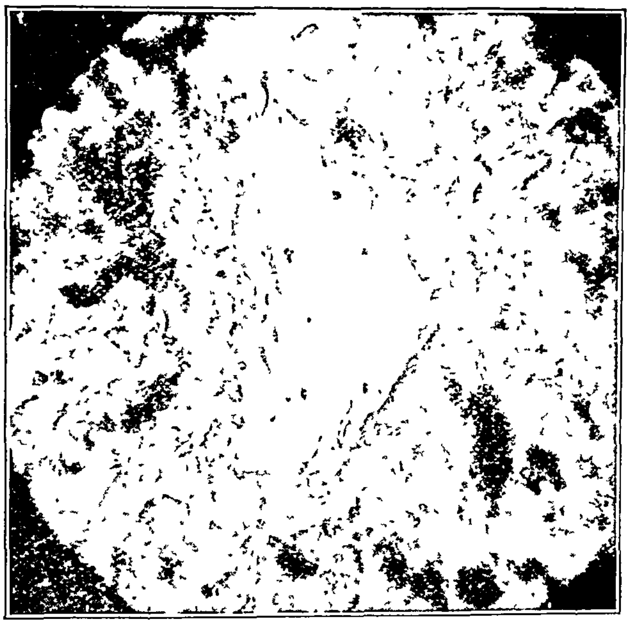

Fig. 2.—Spirochetes clumping in the middle of a lymph space (⅛ inch objective).

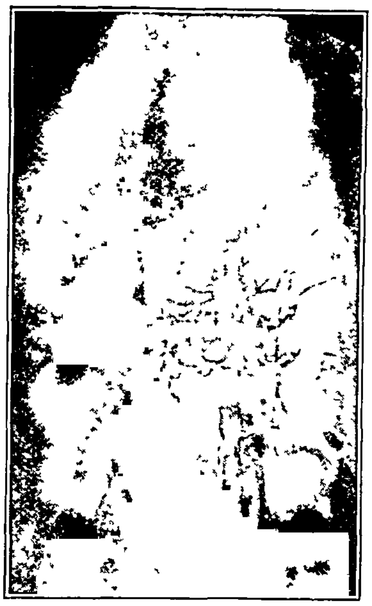

Fig. 3—Clump of spirochetes in the middle of a lymph vessel.

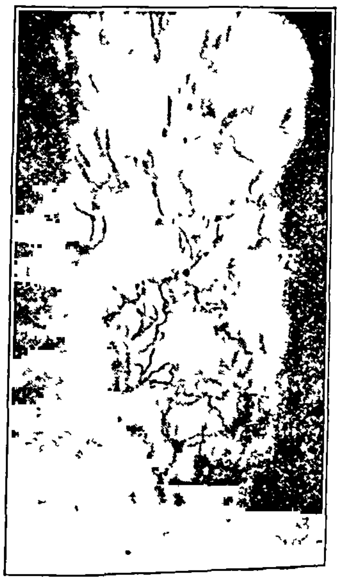

Fig. 4. — Spirochetes clumped together in a lymphatic gland of the groin.

The swelling of the glands, which is the result of tuberculous or of mixed infection, has no connection with the enlargement due to the invasion of the spirochetes, and the latter then constitute a complication by themselves.

According to Gastou, the evolution of syphilis can be schematically reduced to three periods, one lymphatic in its development, a secondary one with manifestations on the capillary and venous system, and finally an arterial infection of a tertiary nature. It seems that the treponema changes its functions and undergoes modifications after some time, so much so as to cause a difference in the symptoms. In fact, according to Gastou, the treponema at the beginning of its existence seems to be an anaërobe, and is gradually changed into an aërobe. The eruptive symptoms of syphilis, beginning with the chancre and ending with the gummous tumor, are the result of the multiplication of the infectious agent. The reactions caused by its presence in the tissues are the symptoms of the eruption which we see in the syphilitic subjects. In the individual free from syphilis the treponema finds a different reaction from that of the tissues which cause the induration. Finger has experimentally proved the inoculability of the tertiary syphiloma. Hallopeau and Gastou[3] are of the opinion that the difference of symptoms in the various periods of syphilis are due to the different functions and to the different action of the treponema in consequence of modifications. The modified spirochete, when inoculated in a healthy organism, takes again its ordinary appearance and reproduces the initial symptoms.

The syphilitic treponemas find also their means of propagation into the system by continuity through the interstices of the tissues, showing thick syphilitic lesions around the initial lesion which Lang called regional infection. This peculiar method of propagation can, according to Hallopeau, be explained as the result of an increased virulence of the treponema emanating from the initial lesion. It can also be accounted for by a debilitated condition of the general system of the patient, which shows lack of power to produce antibodies in order to impede the progress of the germs.

In the first two cases the chancres had been of an unusual severity and had been accompanied by hard edema of the penis and enlargement of the lymph glands of the groin which Hallopeau very appropriately calls *le ganglion barrière.*

The edematous prepuce and the paraphimosis necessitated circumcision. The skin was removed, together with the ulcerated chancre. The chancre was cut in pieces and stained by the Levaditi method for spirochetes and the microscopic and photomicrographic work was done by my assistant, Dr. George H. Werk.

Figure 1 shows spirochetes free in the interstices of the tissues of the chancre. The reaction does not seem to be very remarkable and the spirilla do not suffer any impediment.

In Figure 2, in the middle of an infiltrated skin surrounded by leucocytes and large plasma cells, a lymph canal is opened containing spirochetes which begin to form lumps.

Figure 3 shows much more distinctly a clump of spirochetes in the middle of the lymph vessel. This bunching of spirochetes in the middle of a lymph canal shows clearly that the agglutinin of the organism has an effective action in massing the spirilla together. This action is also found in the alveoli of the lymphatic glands.

Figure 4 shows a bunch of spirochetes in the middle of an alveolus of the lymph gland, the true syphilitic bubo. This condition of the glands shows that their enlargement in consequence of an invasion of syphilis is not entirely passive but is due to an active reaction for the purpose of opposing the progress of the invading organisms. When the glands have suffered in consequence of suppurative adenitis, or when they have been removed or destroyed, infection with syphilitic virus seems to be much more dangerous because the glands are ineffective and can not impede the progress of the spirochetes.

Hallopeau referred to a case in which a limited thick papular eruption extended for over 15 cm. (6 in.) around the left inguinal region. The inguinal glands had been destroyed by a chancroidal bubo. It seems that in this case the treponema, instead of remaining limited to the gland where it could have been somewhat modified, has been inoculated by continuity and from the interstices of the tissues has traveled forming the limited eruption before the general symptoms have appeared.

The intrusion of the spirochete or its toxic products into the circulation of the blood causes at first a reaction which is revealed by the syphilitic fever. This reaction precedes the roseolar eruption, which may be considered as an effort of the organism to dispose of the invading germs. After the first reaction the system seems to lose the power of generating enough hemolytic elements to counteract the noxious action of the spirochetes. In the same way when the organism is feeble on account of some other diathesis, such as tuberculosis, malaria, or on account of alcoholism and a bad hygiene, the opsonic index is greatly lowered and the organism is left to the mercy of the invading bacteria and to that of the syphilitic virus. On the enfeebled condition of the constitution, the inability of the organism to produce antibacterial elements, and the passive condition of the leucocytes, unable to cope with the virulent germs, depends the factor of malignant syphilis. It is not the quality of the syphilitic virus which is the cause of malignancy, but the condition of the system of the newly infected individual. At times we see cases of very severe syphilis which have been taken from patients who had shown the mildest symptoms.

The treponema, after the first constitutional eruptions, begins to show a tendency to systematize and show up in its preferred localities. At this time the eruptions are no longer symmetrical as they were in the beginning, but make their appearance in places which offer better ground for their development. Other bacilli take part in the work and are the cause of pustular and ulcerative forms of syphilis. External injuries, irritations constantly applied in a part of the body are favorable causes for the invasion and development of the treponema in that locality. For this reason mucous patches of the tongue are so frequent in the mouth of men who chew tobacco.

According to the views of Hallopeau and Gastou the persistency and the stubbornness of the papulo-squamous syphilids of the palms and soles must be due to the hard and thick condition of the epidermis which covers those regions. The treponema, after being carried there by the capillaries, is left in the interstices of the tissues, easily reproduces, and can not find a way to reenter the circulatory path or its way out on account of the thickness of the horny layer. Moreover, the remedial agents in the circulation do not easily reach the palms and soles, nor are the remedies applied on the surface of the skin capable of penetrating the thick epidermis. Consequently the spirochetes remain undisturbed; hence the stubbornness of the affection.

The initial lesion in a severe form is usually a sign of strong reactive power of the system, the spirochetes are surrounded by the leucocytes, the tissues are trying to encapsule them, antibodies are formed and the organism is guarded. A well-directed treatment will easily dispose of the few spirochetes which are still found in the system, and in a short time the disease will die out. On the contrary, a mild initial papula, which in many cases passes unobserved shows that the system is unprepared to cope with the infectious agent. It finds its way more often through the blood vessels, and in a short time the eruptions appear. This kind of initial lesion is the one which is followed by severe and stubborn constitutional symptoms

---

3. Localisations systématisées du tréponème Pallidum, 1907

In reference to the treatment, it is difficult to foresee whether it will be possible to find an antisyphilitic vaccine which, by increasing the opsonic index, will render the organism capable of disposing entirely of the treponema. One thing is sure: that in the mercurial preparations we have a remedy which directly attacks the spirochete and improves the general condition of the system, rendering it able to cope with the virulence of these germs.

In the meantime we can find the means to attack the treponema directly on the initial lesion where it is developing. We can either destroy it in the locality or at least succeed in modifying syphilis to such a point that it may have a mild course. The local and the general action of atoxyl has been greatly praised by Salmon and Hallopeau. The last named author[4] has called its use the novel local treatment of syphilis in its primary period. A salve containing 50 per cent. of atoxyl has been used on the initial chancre and at the same time there have been given injections with an atoxyl solution from 10 to 20 per cent. with satisfactory results.

In my service at the City Hospital in two cases of initial lesion the application of the atoxyl salve dissolved the hardness, cleaned the surface and healed up the ulcer in a much shorter time than has been possible with any other means.

The action of the atoxyl on the syphilitic pathologic products has been recognized by Hoffman[5] not only on man but also on the animals. Hoffman and Uhlenhuth have found in the application of atoxyl a preventive action against syphilis in the animals, and this was later confirmed by Metchnikoff. But it seems that the atoxyl treatment does not protect the patient from the relapses of syphilitic manifestations. In my practice the atoxyl injections in cases of severe symptoms did not give me the results which the mercurial preparations have afforded. We can say then that to-day we believe there has been found another remedy which has antisyphilitic action. Time and experience will show whether it is to replace mercury, whether it is to be given in conjunction with mercury, or whether the greatest of all antisyphilitic remedies will still be mercury.

5 Garfield Place.

THE INFLUENCE OF THE DISCOVERY OF THE SPIROCHÆTA PALLIDA ON THE TREATMENT OF SYPHILIS.*

JAMES F. BREAKEY, M.D.
ANN ARBOR, MICH.

The brilliant results of the work of Schaudinn and Hoffman, following the researches of so many able investigators, and confirming pre-existing opinions that syphilis was due to a specific micro-organism, are certainly a cause for congratulation on the progress of pathologic study. To the general practitioner, however, it presents the question: "What advantage is gained and what difference should it make in the management of a case of syphilis at any stage?"

This is a pertinent question and deserves consideration. In connection with the recent work done by French investigators in the prophylaxis and treatment of syphilis by calomel ointment and atoxyl, a partial answer to the question is found. Metchnikoff[1] has conclusively shown that syphilis may be aborted by the inunction of calomel ointment, provided it be used sufficiently soon following inoculation. Such a prophylactic use of the ointment, while interesting and useful on rare occasions, is impracticable and of no service in general practice; nor can it be used in any case in which a diagnosis has been made by the demonstration of the presence of the *Spirochæta pallida*.

In the same article the abortive power of atoxyl in syphilis was proved. With this drug the interval elapsing between the time of the inoculation and the use of the drug was much lengthened, such an interval having been as long as fifteen days, following which no manifestations of infection appeared. This again, as in the prophylactic use of calomel ointment, is an interesting fact, easily demonstrated in laboratory experiments, but of little more service in general practice than the use of the calomel ointment, so far as aborting the disease following a laboratory diagnosis with the presence of *Spirochæta pallida*.

Among the various laboratory experiments on apes, two animals were inoculated, together with controls, with syphilitic virus and later given prophylactic doses of atoxyl. The control animals contracted the disease, while the two inoculated animals did not. After an interval of two to three months these two apes were reinoculated and both developed typical primary sores. These experiments went to show that after the first prophylactic dose of atoxyl there is neither a dissemination of the virus nor a lasting immunity.

If further work goes to demonstrate the truth of the claims of these men as to the prophylactic power of atoxyl, given soon after inoculation, such a fact can be made of practical use in one way at least. If all persons who have been exposed to a possible syphilitic infection were to submit themselves for treatment by prophylactic doses of atoxyl, it would be possible to wipe out the disease. Such a line of treatment, however, would have to be instituted before the infection had been generally disseminated and before its presence could be demonstrated by finding the *Spirochæta pallida*. In general practice, of course, such a line of treatment would be purely empiric and the infected and uninfected must needs be treated alike. In this connection it might be said that such a dose of atoxyl, however, is harmless.

The prophylaxis and the treatment of an actually existing syphilis, of necessity, are two different things. Having a patient presenting a suspicious lesion, what is the general practitioner to do in the light of present knowledge? Weight of authority up to this time has held that no constitutional treatment should be begun until the diagnosis is confirmed by the appearance of secondary symptoms in some form.

In the presence of a lesion, to-day, in which an unsuccessful search for the *Spirochæta pallida* has been made, it would seem that the active constitutional treatment should still be delayed, pending confirmation of the diagnosis. With such a lesion, scrapings from which show the *Spirochæta pallida*, their presence is of sufficient confirmative weight to warrant the immediate institution of antisyphilitic treatment. Again the question arises: "Of what advantage is this to general practitioners, practically none of whom are able to demonstrate or differentiate the *Spirochæta pallida?*" Granting, however, that the micro-organisms have been demonstrated, what difference will it make in the line of treatment? The primary lesion from which you can first recover the *Spirochæta pallida* is but the first anatomic evidence of a condition already more or less systemic and unquestionably disseminated quite beyond the localized area of the primary sclerosis.

---

* Read in the Section on Cutaneous Medicine and Surgery of the American Medical Association, at the Fifty-ninth Annual Session, held in Chicago, June, 1908

[1] *Ann. de l'Inst. Pasteur*, October, 1907.

What has been previously demonstrated as to the inadequacy of surgical excision in such lesions is quite as true to-day as ever. The only change from preexisting methods of treatment which could be wrought by the finding of the *Spirochæta pallida* would be in advancing the time in which one would feel warranted in beginning constitutional treatment, and even then one of the chief objections to early constitutional medication previously existing would still hold true; that is, early mercurial treatment may abort or delay secondary symptoms and the patient be lulled into a false sense of security after an insufficient course of medication and ultimately develop serious after-effects as a result of medication early instituted following a microscopic diagnosis of syphilis.

If, however, further observations go to show that atoxyl eliminates all evidences and possibilities of a lasting syphilitic disease, then surely much will have been gained.

A study of an exhaustive article by Paul Salmon[2] on arsenic in syphilis leads one to a conviction of the sincerity of its author and the truth of his claims regarding the results of the administration of atoxyl in syphilis. From it the following observations and conclusions may be made:

Atoxyl must be admitted to an equal footing with mercury as a specific in syphilis, and as an abortive in the disease it is much more reliable. As a remedy it is preferable in all stages and possibly can be depended on to destroy all spirochetes if used even after the primary manifestation. It is of special service in the graver and more malignant types of the disease. It is not contraindicated in the parasyphilitic manifestations, but even ameliorates many of the symptoms, such as pains and neuralgia in tabes and paresis.

Syphilis may be aborted by the prophylactic use of atoxyl administered as late as from one to two weeks following inoculation. The failures of previous investigators along these lines have largely been due to insufficient doses of atoxyl.

That atoxyl administered by injection proves to be a true prophylactic is demonstrated by the fact that an animal in which syphilis has been aborted by atoxyl, and later was again inoculated with syphilis, developed a typical chancre. The same experiment goes to show that prophylaxis does not carry with it an enduring immunity.

In the use of the remedy, during any of the stages of syphilis, more rapid improvement than one gets from the use of mercury usually followed.

When the disease has become disseminated—that is to say, at any time following the appearance of the primary lesion—constitutional treatment, be it with atoxyl or mercury, must be carried on for a prolonged period, and, while the improvement of particular syphilitic manifestations is more rapid with atoxyl than with mercury, recurrences appear on the cessation of the treatment.

The explanation of the action of mercury or atoxyl on the spirochete must still be found. It is probably through the effects of the drugs in attenuating the germs or in stimulating phagocytosis.

Beyond a certain dose, the amount given has no further effect on the destruction of the micro-organisms. The small doses are ineffective and useless, while large ones produce toxic effects, varying from slight headache, nausea, vomiting, colic and possibly ocular effects and subsequent paresis.

The ordinary dose should be 50 centigrams. This should be given hypodermically at intervals of one or two days and repeated from four to eight or ten times, after which an interval of rest should be observed, or treatment may be continued by one of the other specifics of mercury or iodin.

Very good results have been observed in the alternation of these remedies, or even in using them together at the same time. At present, atoxyl, as a remedy, promises much.

In unusual dermatoses of uncertain character, the recovery of the *Spirochæta pallida* establishes a positive diagnosis and indicates the necessary treatment. The failure to find spirochetes, however, proves nothing and we are then no better off than we were years ago. In such cases, the Wassermann test may be used as a necessary diagnostic resort.

Outside of the larger medical centers, such diagnostic measures are quite impracticable, and in the hands of the general practitioner impossible. The fact remains that in many cases a diagnosis must and will depend entirely on the clinical picture presented.

To the attending physician still remains the necessity of recognizing syphilis from the symptoms manifested by the patient.

The discovery of the *Spirochæta pallida* undoubtedly marks one of the greatest steps forward in the knowledge and literature of syphilis. The immediate practical benefit of this discovery, however, will be limited to a comparatively few cases, and even in these few cases its presence usually seems to be a confirmatory evidence of a diagnosis previously made by the clinical presentation.

213 East Huron Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BREAKEY AND RAVOGLI.

Dr. Hermann G. Klotz, New York: My experience with primary sores of syphilis has been very similar to that of Dr. Ravogli. I particularly recall one case of a very malignant type in which the primary lesion consisted of a slight abrasion which healed within a week and which I had not recognized as a chancre at all. In connection with Dr. Breakey's paper, I emphatically warn from depending too much in practice for the present on these new discoveries. In time we shall learn more about the spirochete and about the part it actually plays in the development of syphilis, but it is much too early to draw practical conclusions. Long before the spirochete was discovered we knew that some micro-organism must be the causal factor in syphilis, but from clinical experience most syphilologists had come to the conclusion that it was safer to wait until the secondary symptoms appeared before beginning treatment. Until we know more about the spirochete and its life history there is no reason to recede from the former practice. From clinical observation we knew, long before this fact was explained by the study of the life history of the malaria plasmodium, that quinin was most effective in malaria if given at a certain time. So in time we may learn why the results of the mercurial treatment are more favorable when it is withheld until the secondary symptoms have appeared.

---

[2] Ann. de l'Inst. Pasteur, January, 1908.

Dr. William A. Pusey, Chicago: I endorse Dr. Klotz's caution against attaching too much importance to the spirochete in a diagnostic way. I also protest against the present vogue of atoxyl. There is no reason to believe that arsenic is more efficient against syphilis than mercury, or that there is anything except arsenic in atoxyl that could be beneficial in syphilis. The only claim for the preparation is that by it arsenic can be given in enormous doses, but it is not established that the molecule of atoxyl has the same therapeutic effect as arsenic. There are a variety of opinions as to the safety of the preparation; dangerous results have been reported from its use, and the testimony regarding it is not all in accord. I believe that we are not justified in relying on it to any extent in the present state of our knowledge regarding it. Metchnikoff believes that syphilis can be aborted by the use of a calomel ointment, and certain French writers assert that this is efficacious when applied within eight hours after exposure. The statement that atoxyl or any other preparation of arsenic will abort syphilis if used within fourteen days or even longer after exposure is, in my opinion, absurd. If mercury will not do it—and it will not—there is no reason to believe that a new preparation of arsenic will display such potent action against syphilis.

Dr. A. Ravogli, Cincinnati: I do not in my paper recommend the use of atoxyl. I selected six cases of recent syphilis in my hospital service and subjected the patients to three injections per week of a syringeful of a 10 per cent. solution of atoxyl; one of these patients developed an iritis, and the others were at times a little better, at times a little worse. I then changed the injections to bichlorid, and my experience showed that the three weeks I had devoted to atoxyl treatment had been wasted. After three injections of bichlorid the eruption in all the cases cleared up. Atoxyl, used locally, seems to hasten the healing of a hard chancre. Calomel would probably have the same result. My experience has led me to take a lukewarm attitude toward atoxyl.

HEMOLYSIS WITH SPECIAL REFERENCE TO CANCER AND TUBERCULOSIS.

FURTHER OBSERVATIONS ON ITS CLINICAL ASPECTS*

GEORGE W. CRILE, M.D.
CLEVELAND.

The literature of the work hitherto done to discover some blood test for cancer is presented by Richard Weil.[1] The technic followed in our work at Lakeside Hospital is based on that in current use, modified to meet clinical requirements.

I have heretofore reported for the American Society of Cancer Research our observations on hemolysis in malignant tumors. This is in the nature of a report of progress in our investigation. The technic has been greatly improved and now seems to be quite accurate. It is exacting, must be precisely done, and every step amply surrounded by checks and controls.

Dr. D. A. Prendergast made the first series of observations, after which Miss Ora Lewis took all the responsibility of the technic for seven months and made many improvements during the period of her painstaking work. Dr. A. M. Tweedie has been carrying on the work since Miss Lewis' service and has made extremely valuable suggestions and alterations in the technic. My resident physician, Dr. H. G. Sloan, and members of my staff at Lakeside Hospital, Drs. Gamble, Eisenbrey and Pomeroy, have assisted in the clinical side.

THE NATURE OF HEMOLYSIS.

The red corpuscle is covered by an exceedingly thin and delicate membrane, which prevents the escape of its contents, the most important being hemoglobin. This investing membrane is very susceptible to chemical or thermal changes in its environment. If impaired by such changes a part or all of the hemoglobin will escape and become freely diffused in the serum. The corpuscles then become proportionately paler, and if all the hemoglobin is lost there will remain only the framework of the cell, designated as "shadow cell" or "ghost."

Free hemoglobin may be detected in the urine and other secretions. If in quantity, it stains all the tissues, causing a brilliant jaundice. This process is known as hemolysis and the agents causing hemolysis are known as hemolysins. Hemolysins may be roughly classified as inorganic and organic. Among inorganic hemolysins are ammonia, soaps, ether—any agent that will change the isotonicity of the blood serum. Among organic hemolysins are normal blood and tissue juices of alien species, and blood and tissue juices in certain pathologic states. In pernicious anemia, in certain fevers, occasionally in chronic suppuration, and in other general diseases there is such a change in the blood serum that when the red corpuscles from normal individuals are suspended in this serum hemolysis occurs. It may be at once asked why such hemolytic serum does not destroy the corpuscles of the patient *in vivo*. Two reasons suggest themselves why this does not always occur. The first is that the corpuscle undoubtedly shares the universal attribute of living matter whereby it is able, to a certain degree at least, to adapt itself to its environment. The second reason why hemolysis may not occur in the presence of hemolytic serum is that the process *in vitro* is not identical with that *in vivo*. A corpuscle, having adapted itself to a certain environment, may itself become so altered that when it is again suspended in normal blood serum it may undergo hemolysis.

The medical importance, if any, that these facts assume is determined by correctly answering the following questions: Is there a reliable technic for the determination of hemolysis? Are the changes in the serum and in the corpuscles thus produced by disease of a specific nature? Are they constantly present?

CONDITION OF THE TEST.

Many difficulties beset the technic. There are many inorganic hemolysins that must be avoided. The blood must be drawn and kept absolutely free from these. Red blood cells are extremely sensitive to changes in temperature. Provision for absolute control of the temperature must be made. As the corpuscles are very delicate, extreme care must be exercised in applying the mechanics of the technic. Experience has shown that if the serum and corpuscles are immediately separated, either by drawing the blood in sodium citrate solution or by immediate centrifugalization, the hemolytic action is either minimized or negative. The maximum reaction is obtained when the serum and the corpuscles are separated by clotting. The serum attains its maximum hemolytic power in about twenty-four hours. In securing normal blood one must bear in mind the fact that it is not possible absolutely to determine, except by an actual blood test, whether a given individual's blood will react as normal. But if these samples of supposedly normal blood are used and are tested against each other as well as against the blood of the patient, there is then but slight chance for error. Again, it has been shown that organic hemolysins are destroyed, hence rendered inert, by a temperature of 55 C. for ten minutes. Anticipating for a moment a part of what I shall say as to the results of our tests, I will state that in every instance this temperature destroyed the hemolytic power of the serum. The hemolysins of disease, so far as we have studied them, are of organic nature. Inorganic hemolysins, such as ammonia and other chemicals, are not influenced by heat. If, then, all the tubes of the entire test are made up in duplicate and one set subjected to a temperature of 55 C. for ten minutes, possible error from inorganic hemolysins may be excluded.

---

* Read before the American Society of Obstetricians and Gynecologists, Baltimore.

[1] Jour. Med. Research, October, 1908.

The test is determined by noting the result of suspending normal red cells in the patient's serum and suspending the patient's cells in normal serum.

TECHNIC.

The technic in detail is as follows:

Facilities Required.—(a) incubator; (b) refrigerator: (c) centrifuge: (d) sterilizer; (e) one gross test-tubes, size one-half inch; twenty-four tubes, three inches long, one-fourth inch inside diameter; (f) test-tube racks made to hold seventy-two tubes, with each tube hole numbered consecutively in ink; (g) glass beads for defibrinating the blood; (h) several aspirating needles, with stylets.

Comment.—These tubes must be cleansed in isotonic salt solution only. The tubes to be set up in the test should be kept immersed in isotonic solution and taken out only when they are to be used. The large tubes that are used to collect the blood are cleansed with isotonic solution and dried. These tubes are used in pairs—one for obtaining the blood for the cells (in this tube a glass bead is placed), the other for blood for the serum. Both tubes are then closed with cotton stoppers wrapped in close-mesh cotton cloth, sterilized, and set aside for future use. Needles are similarly wrapped in individual packages and sterilized.

Obtaining the Blood.—The blood is drawn by aspirating a vein. The most convenient vein is usually the median basilic at the bend of the elbow. The field is scrubbed with soap and water, followed by ether and alcohol, then thoroughly cleansed with sterile water or, better still, with salt solution. The arm is firmly compressed well above the elbow by bandage or otherwise to dilate the vein. The needle is then inserted through the skin into the vein. Into the tube containing the bead 3 c.c. of blood are collected and the tube immediately and continuously agitated for about ten minutes. Defibrination of the blood is thereby accomplished. Into the other tube are drawn 10 c.c. of blood. This tube is kept at rest in a slanting position during the separation of the blood into clot and serum. If it can be conveniently done, it is better to secure the blood for the cells just before the tubes are to be set up, that is, about twenty-four hours later than the blood is drawn for the serum. The pressure from the arm should be removed before the needle is withdrawn: otherwise a greater amount of blood than is necessary will ooze from the puncture in the vein. The further preparation of the blood consists in putting the defibrinated blood into a tube containing 20 c.c. 0.85 per cent. saline solution made up with distilled water. This tube and the one containing the clotted blood are now placed for approximately twenty-four hours in the refrigerator. Cold facilitates separation of the clot and serum and preserves the blood. The separated serum is pipetted off, put into a sterile tube and again returned to the refrigerator. In precisely the same manner blood is taken from two or three apparently normal individuals and subjected to precisely the same technic. The supernatant fluid in the tube containing the corpuscles is poured off and 20 c.c. of fresh isotonic salt solution is added to each tube. The tube is then gently shaken until the cells are in complete suspension. The suspension fluid is now transferred to the various sera according to the formula.

Setting Up the Test.—We then have the corpuscles and the serum from four individuals, the patient and three supposedly normal individuals. Using the smaller test-tubes, 0.5 c.c. of the serum of each is added to 0.5 c.c. of a suspension of the red corpuscles of A, B, C. and D in 0.85 per cent. isotonic salt solution. The same is done with the serum B, C and D. The tests are put up in duplicate. The duplicate set is taken out of the refrigerator and placed in a water bath for ten minutes at 55 C. As previously stated, this destroys all organic hemolysins and constitutes a control in the technic. Testing the patient with three normals requires the use of thirty-two tubes arranged as follows:

Tube.		
1.		Serum A + cells of A
2.	(heated)	Serum A + cells of A
3.		Serum B + cells of B
4.	(heated)	Serum B + cells of B
5.		Serum B + cells of A
6.	(heated)	Serum B + cells of B
7.		Serum A + cells of B
8.	(heated)	Serum A + cells of B
9.		Serum C + cells of C
10.	(heated)	Serum C + cells of C
11.		Serum C + cells of A
12.	(heated)	Serum C + cells of A
13.		Serum C + cells of B
14.	(heated)	Serum C + cells of B
15.		Serum A + cells of C
16.	(heated)	Serum A + cells of C
17.		Serum B + cells of C
18.	(heated)	Serum B + cells of C
19.		Serum D + cells of D
20.	(heated)	Serum D + cells of D
21.		Serum D + cells of A
22.	(heated)	Serum D + cells of A
23.		Serum D + cells of B
24.	(heated)	Serum D + cells of B
25.		Serum D + cells of C
26.	(heated)	Serum D + cells of C
27.		Serum A + cells of D
28.	(heated)	Serum A + cells of D
29.		Serum B + cells of D
30.	(heated)	Serum B + cells of D
31.		Serum C + cells of D
32.	(heated)	Serum C + cells of D

Determination of Hemolysis.—The tube subjected to a temperature of 55 C. should be placed in the refrigerator long enough to acquire the same temperature as all the other tubes. All the tubes are now taken out of the refrigerator and placed in a thermostat at a temperature of 37 C. for two hours. At the end of this time they are again placed in the refrigerator for twenty hours. At this time the hemolysis may be determined. This, of course, is indicated by the pink coloration of the supernatant fluid and the condition of the sedimented cells. Accurate notes of all the cases are kept by the numbers on the tubes. The result is read off by members of the staff who have no knowledge of the identity of any of the tubes. These observations make up the tables to be presented.

RESULTS OF STUDY.

Many changes were made in the technic until the present was attained. The results are now usually uniform. Our particular study was directed toward the hemolytic reaction in the normal state, in pyogenic infections, in malignant tumors, in benign tumors and in tuberculosis.

Among miscellaneous cases there were nine instances of hemolysis, two in cases of grave eclampsia, one in a case of extreme hyperpyrexia due to hyperthyroidism several hours before death (the temperature at this time was 109), in one case of leukoplakia of the tongue, and in one case of psoriasis. The remaining four occurred in cases of chronic diseases without definite diagnosis.

The results of our study may be tabulated as follows:

Total Number of Cases Studied, 591.

		Hemolysis.	
		No.	P.C.
Normal subjects	211	0	0
Pyogenic infection	71	7	10
Benign tumors	55	0	0
Cancer	153	130	85
Postoperative cancer cases with clinical recurrence	11	11	100
Postoperative cases without clinical recurrence 3 weeks to 15 years after operation	37	0	0
Tuberculosis	52	48	92

Extracts of malignant tumors uniformly caused total hemolysis. Extracts of benign tumors uniformly caused no hemolysis.

COMMENTS.

The cancer cases showing no hemolysis were mostly in the advanced *inoperable stage*. Only *an occasional* early case failed to show hemolysis.

Cancers on mucous membranes showed hemolysis more frequently than cancer in tissue, as the breast.

All cases of tuberculosis showed reverse hemolysis, that is, normal serum hemolyzed the *patient's* corpuscles. In all cases serum heated to 55 C. for ten minutes prevented hemolysis. Sudden chilling of the blood according to the method of Hoover and Stone caused a marked increase in the hemolytic action. Plasma obtained by *immediately centrifugalizing* the serum caused little or no hemolysis in hemolytic cases.

The hemolytic property reaches its maximum about twenty-four hours after the blood is drawn.

In the cancer group the cases in which the disease was entirely removed lost their hemolytic *property in from* twelve to twenty-one days after operation.

In cases in which an incomplete operation was performed the hemolysins continued indefinitely.

CONCLUSIONS.

Our conclusion is that hemolysis occurs in a number of diseases. It occurs in great frequency in cancer and tuberculosis. The reaction in tuberculosis is the reverse of that for cancer. From the clinical standpoint hemolysis offers *additional evidence* which may be used in the diagnosis of cancer or tuberculosis. This evidence is not as yet specific.

THE VALUE OF A ROUTINE PHYSICAL EXAMINATION.*

EDWIN W. GEHRING, B.S., M.D.

Instructor in Physiology, Medical School of Maine; Adjunct Physician to the Maine General Hospital, Portland; Physician to Portland Tuberculosis Class.

PORTLAND, MAINE.

One gets the impression from reading certain books on general medicine that diagnosis constitutes three-fourths of the physician's work, and that having ascertained the nature of a patient's ailment, anyone can institute treatment. However widely we may dissent from this view, we must concede the important part played by diagnosis in prescribing for our patients, to say nothing about the intellectual stimulation it affords the practitioner. In itself it is so absorbingly fascinating that the Germans, for example, may be said to look on it as an end, rather than as a means to an end, and to concern themselves not with the treatment suggested but with the autopsy to confirm or to disprove their original findings. Nevertheless, for all of us, the recognition of disease from symptoms is essential for skilful, clear-headed management of any case, symptomatic prescribing being unscientific and unjustifiable save in rare instances. Convulsions, dyspnea, diarrhea, cardiac palpitation are symptoms, for which one should seek the underlying cause, rather than adopt palliative measures whose effects, at best, are transient.

The word "diagnosis," as I use it, includes the recognition of physical signs of disease, a careful discrimination among and weighing of these, and a final arrival at the true nature of the affection in question by consideration of signs in connection with the history of the case. Anyone who has read many such case histories and records of physical examinations with probable diagnoses, and who has then been fortunate enough either to see or to read accounts of autopsies on the bodies of these same patients, must have *been impressed with the* discrepancy which too often exists between antemortem and postmortem discoveries.

About a year ago it occurred to me that a review of many cases might afford some explanation of our mistakes. *Accordingly, since that time I have studied one* hundred instances of disease, some of which came to autopsy, others being ultimately diagnosticated and successfully treated. The revelations of this work suggested the title of my paper, for, among other causes to which our errors may be *attributed, the following seemed most* prominent: First, lack of clinical, book and laboratory knowledge; second, untrained powers of observation; third, absence of system in obtaining histories and making physical examinations; fourth, inability to interpret data secured; fifth, the fact that the problem is incapable of solution.

I have attempted a consideration of just one part of one of these causes—the lack of systematic physical examination. In the series of cases investigated, typical *of what the average general practitioner* sees, as many failures in diagnosis could be assigned to this as to any other one cause. Both radials were not palpated simultaneously, the gums were entirely overlooked, no count was made of white blood corpuscles, the urine was not examined for sugar. This fact is all the more deplorable because a habit of routine work can be acquired by everyone, a fact which is not in the same degree true of the acquisition of knowledge, or of the power to observe, or, having seen, of the ability to interpret. The haphazard, accidental method of procedure is always productive of *confusion and error*, rather than conducive to enlightenment, accuracy, and truth. To bring *forcibly to mind the real value* of routine work, I have chosen several cases in which diagnostic blunders were the direct result of no regular order or plan of examination. Histories and results of examination are stated precisely as in the original.

Case 1.[1]—Male, aged 32, occupation cook, came to the hospital on Jan. 6, 1899. His family history was negative and previous history good. He denied any syphilitic infection, but admitted having had urethritis some years previously. He had never had an attack similar in character to this. The present illness dated from Dec. 30, 1898, eight days before applying for relief at the hospital. The first symptoms seem to have come on rather suddenly with a rigor of marked severity, followed by fever and later by profuse sweating. Almost immediately afterward he was seized with intense muscular pains, extending over the trunk and limbs; these pains were agonizing in character, increased on the slightest exertion, and had been present with varying degrees of severity until his admission. They prevented him from sleeping, and he spoke of them as being not unlike rheumatism—dull and aching while he was in the recumbent posture, becoming intensely lancinating as soon as the slightest exercise was attempted. His appetite, which had previously been of the best, was absolutely lost and he had eaten nothing for three days. With the exception of some slight frequency of micturition and a slight cough with expectoration, there was nothing else of importance in the history of the illness.

---

*Read before the Maine Medical Association at Bangor, Maine, on June 11, 1908

[1] Cases 1, 2 and 6 are taken from Cabot's "Case Teaching in Medicine."

Examination.—The patient is a rather large, well-formed man, the mucous membranes are of a good color, tongue moist, coated with a white fur. The eyes are markedly injected, the eyelids slightly but distinctly edematous, and an erythematous area is present above the swellings. Negative results are obtained everywhere on auscultation and percussion, except at the bases of both lungs posteriorly, where a few moist râles are heard. The heart sounds are clear. The liver and spleen are not palpable; the abdomen is soft and natural in appearance, negative results being obtained on palpation. No rose spots are seen. There is no superficial glandular enlargement. Pulse 100, respirations 24 a minute. Later the temperature ranged in the vicinity of 103 F. for three weeks and then gradually subsided. The urine is normal in color, acid, specific gravity 1.026. Microscopicallly, it shows pus corpuscles in considerable quantity, epithelial cells and a few mucous cylinders.

From such data can we solve the problem? Severe pains in the trunk and limbs accompany such infectious diseases as influenza, tonsillitis, dengue, variola, trichiniasis, and yellow fever. Muscular rheumatism can not be ignored; it is a common diagnosis of the real condition existing here. Can one exclude neuritis? Certainly not if the knee-jerks are diminished or absent, in which event tabes and anterior poliomyelitis also come to mind. Note that in the original examination no attention was given the gums, pupils, throat, blood, reflexes, or the urine for sugar. These were all subsequently found to be normal except the blood, which showed a leucocytosis with normal hemoglobin. The increased white count suggested a differential count, which, in its turn, revealed eosinophilia. Excision and histologic inspection of a bit of biceps muscle demonstrated trichinæ.

In the clinic of Dr. Adler at the German Hospital, New York, eight cases of trichiniasis with eosinophilia were admitted between Nov. 1, 1905, and Feb. 1, 1906. Trichinæ could be seen in the muscles of only three of these, yet all showed areas of infiltration and muscle fiber degeneration. To quote Ottenberg: "The combination of eosinophilia with edema of the face, which occurred in six of the above mentioned cases; muscular pains, present in all, though pronounced in only two; and fever, occurring in seven cases, makes a clinical picture which could hardly be exhibited by any disease other than trichiniasis." In his mind, "there is no doubt that when blood examinations are not made, many, if not all, particularly of the mild cases of trichiniasis, are mistaken for other affections, notably typhoid, intestinal intoxications, muscular rheumatism or influenza. Indeed, in the eight cases here recorded, six patients were admitted to the hospital as probable cases of typhoid, one as a case of muscular rheumatism, and only one with a suspicion of trichiniasis."

In temperate climates trichiniasis is the only chronic febrile disease with eosinophilia and severe muscular pains. Blood examination, therefore, renders the diagnosis comparatively easy. In the tropics other fevers accompanied by the presence of intestinal parasites complicate the situation; but in any climate these cases so closely simulate typhoid and muscular rheumatism as readily to be mistaken for either without blood examination.

CASE 2.—A boy, 14 years old, of gouty family history, complains for a year of frontal headache, not very severe, but persistent and wearing. Appetite excellent, but digestion not as good as it has been. Has suddenly grown very irritable, having previously been sweet tempered. He has lost flesh during the year and seems listless and weak. Sleeps well. Bowels somewhat constipated. Getting pale. Heart, lungs and abdomen negative. Knee-jerks not easily obtained, but gait shows weakness. Urine, normal color, acid, 1.028, no albumin. Sediment negative. Temperature 98.0, pulse 96, no edema, blood negative.

This sounds complete, but it lacks the very points which make a diagnosis possible. We consider the various causes for change in disposition, and find them enumerated as masturbation, brain tumor, diabetes, psychosis of puberty. Eyestrain, adenoids, frontal sinus disease, malaria, pubescence, are considered as possible causes of frontal headache in a boy of fourteen years. The significance of pallor is dwelt on; we reflect on loss of flesh despite good appetite, together with persistent headache and diminished knee-jerks.

Two facts not mentioned in the attending physician's report, and, therefore, omitted from the above quoted history, now come to light under the routinist—the quantity of urine passed in twenty-four hours, three quarts; and the amount of sugar in that urine, 5 per cent. The glycosuria, being persistent, denoted diabetes mellitus.

CASE 3.—A male child, 10 months old, was brought to the Infants' Hospital in Boston from a town twenty miles distant. The physician accompanying it said that he had seen the infant daily for one week, during which time its upper extremities were habitually extended over the head. Any attempt at moving them was resented by infantile shrieks. The child had been receiving a sterilized milk mixture which it had taken with avidity, and was apparently content when not disturbed. The diagnosis was double dislocation of the shoulder joints, and for their reduction the little patient had been sent to a hospital.

Further Examination.—Another student and myself were given an opportunity, through the courtesy of Dr. Stone, of verifying the diagnosis and we failed to do so. We did note, however, an unmistakably rachitic head, a slight rosary, and somewhat enlarged epiphyses; the eyes presented nothing remarkable, but, unfortunately for the first man's reputation for thoroughness, the gums were spongy and bleeding.

Treatment.—Under the circumstances it was deemed wise to heed the call for a different diet and orange juice. In less than two weeks' time the child moved all its extremities freely.

My point is that any person who had acquired the habit of examining patients systematically would have diagnosticated scurvy at once. For this and other reasons I have since that time included the gums in my routine examination of every patient.

CASE 4.—A prominent medical consultant of my acquaintance in the middle west was one day asked by a practitioner in an outlying town to see with him one of those cases of malaria which prove the "non-specific action of quinin in that disease," to use his own words. The history, in brief, was that of one who had had regularly recurring chills every second day for three weeks, during which time quinin powders had been used faithfully without the slightest effect on the course of the disease.

Examination.—The consultant went in search of these remarkable malarial plasmodii armed with microscope, cover-glasses and slides, blood-stain and a Talquist scale. At 4 p. m. the patient was found feeling chilly, temperature 100.9 F., pulse 88. Eyes, throat, gums and ears were normal. Marked pallor formed the background for the faintest flush over the cheek bones. A drop of blood from the ear showed hemoglobin, 90 per cent., and a similar drop under the microscope proved positively the absence of malarial organisms. Examination of the lungs, including inspection, percussion, palpation, whispered voice, was unsatisfactory. Auscultation disclosed below the right clavicle persistent, localized, cog-wheel respiration, indicating a partial obstruction of alveoli to the entrance of air. The remaining examination of the heart, arteries, liver, spleen, kidneys, glands, tendon reflexes and urine was negative. Potassium iodid, ten grains after meals, was ordered, and produced at the end of one week sputum containing tubercle bacilli.

Here, then, is a sample of a snap diagnosis based on regularly recurring chills without making any examination whatever.

The case also explains the origin and suggests the worth of reports, occurring not infrequently in our journals, concerning the non-specific action of quinin in malaria. Three lessons are suggested: first, the value of a routine physical examination; second, that from the blood only can a positive statement be made regarding the presence of the malarial organism; third, an intermittent fever which resists quinin in capsule is not of malarial origin.

Case 5.—A consultant was called to see a case of convulsions with anemia in a woman of 40. We must admit the condition unusual if convulsions and apparent anemia were the only symptoms, but one can not sympathize with a man who failed to diagnosticate a disease so easy of detection as this one proved to be, because he had not examined thoroughly.

Conditions Considered.—He had considered the various causes of convulsions: uremia and hepatic toxemia, cerebral concussion or compression, diabetes, epilepsy, hysteria, sunstroke, syncope, opium, alcohol or gas poisoning and even apoplexy. None would fit. Anemia was taken for granted because of paleness. Routine examination should include inspection of the gums, where, in this instance, with the aid of a pocket magnifying glass, was found the so-called "lead line," which is not a line at all. This suggested blood smears and stippled red cells were at once discovered; hemoglobin, 90 per cent. And yet the woman was said to be anemic!

Lead Poisoning.—The "lead line" was also found on the gums of the three children of the family, and in all probability would have appeared on the father's had not his teeth been false.

Emphasis is again laid on the word "routine." Did we all have some definite, comprehensive scheme of procedure and follow it in every case, I should not in the past have been able to diagnosticate plumbism in two persons, each of whom had previously consulted two different members of the metropolitan profession for the same ailment. This case also calls to mind, as did Case 2, the wholly unjustifiable diagnosis of anemia because of paleness. Pallor may mean anemia, but often does not. Consumptives, neurasthenics, persons with deficient skin circulation are pale, but few of them are anemic. The Talquist hemoglobin scale alone can decide in the vast majority of instances.

Case 6.—A painter, 23 years old. Family history negative. General health always good. Gonorrhea eight months ago, a slight mucopurulent discharge still persisting. Seven months ago had an attack of colic, lasting three or four days, similar to his present trouble, but less severe. Bowels move once daily without medicine. Seven days ago began to have cramps which have grown rapidly worse since and have been only partially relieved by large doses of morphin and atropin. The abdomen at first was generally tender, especially just to the right of the navel. The bowels have been constipated during the present illness, in spite of repeated doses of salts and enemata. Very little gas passes by rectum. Has vomited three times, the vomitus containing nothing of note.

Examination.—Examination shows a poorly nourished man, suffering acutely from general colicky pains in the abdomen. Expression pinched and anxious. No jaundice. Faint blue line on gums. Radial arteries slightly thickened. Heart and lungs normal. Abdomen distended and tympanitic. Between attacks of pain no marked tenderness is elicited even on fairly deep pressure. The distended, moving coils of intestine are visible through the thin abdominal walls, which are somewhat rigid everywhere. The finger high up in the rectum strikes a tender point a little to the right of the median line. The pulse is small and has been steadily gaining in frequency. The temperature taken only during the past five days has never gone above 99.0 degrees. Urine scanty, acid, high-colored, specific gravity 1.026. No sugar or albumin. Sediment negative. Leucocytes five days ago 35,000, now 19,000.

This case illustrates a mistake frequently made when one of the conditions present is so obvious as to eclipse all others—the failure to consider all the facts presented. Here are the results, for example, of a thoroughly systematic examination. Lead poisoning was so conspicuous that a leucocytosis of 35,000, which never occurs in uncomplicated plumbism, was overlooked and led to serious blunder in diagnosis. That count in conjunction with a steadily rising pulse and a distended, tympanitic, rather rigid abdomen, pointed to a probable focus of inflammation in the abdominal cavity. Operation showed general peritonitis due to appendicitis.

Instances might be multiplied indefinitely to strengthen my contention that for a thoroughly good physical examination some fixed scheme of procedure is necessary. I therefore presume to suggest one which, I feel, ought to be followed in every first examination, at least, in order that by the prominence of one or more symptoms one may not be led astray in his train of thought, may not confine his entire attention to one organ to the exclusion involuntarily of all others, may not render a snap diagnosis because of preconceived opinions.

A minimum examination should include attention to the weight, pulse in both radials at the same time, temperature, hemoglobin, blood; the urine for quantity, albumin, sugar, bile, specific gravity, reaction, and sometimes sediment; the pupils—I would almost add fundus—throat, gums, ears, reflexes, glands; the liver, spleen and kidneys, for palpation; the heart, lungs and arteries.

The tongue's appearance is of so little diagnostic importance that its routine inspection may be omitted. Dyspepsia and a clean tongue indicate hyperchlorhydria, but the so-called typhoid and scarlet fever tongues are not significant.

The hemoglobin test alone can eliminate anemia. If the scale shows less than 75 per cent. of hemoglobin, a blood examination ought to be made. This statement refers, of course, to the possibility of an anemia and does not apply to the making of blood smears to determine the presence or absence of malarial plasmodii, of stippled red cells, of an eosinophilia; or to the leucocyte count for purposes of differentiation between a possible typhoid and a pneumonia or appendicitis or other septic condition; or to the Widal reaction. All of the latter ought to be more generally employed.

Science progresses by additions and subtractions. Nothing better illustrates progress by subtraction than the change which has taken place regarding our conception of what constitutes urinalysis. Formerly these contained references to the various kinds of cells seen, and we thought we knew their source and significance. To-day an excess of cells means exfoliation or inflammation somewhere in the genitourinary tract, the precise location being determined, if at all, by the patient's symptoms. We don't know the difference between a lymphocyte and a renal cell, hence it is more correct to speak of cellular than of epithelial casts. The various kinds of crystals are of just as little importance as cells. Hyaline and even finely granular casts may be found in any urine. One swallow doesn't make a summer or one cast a nephritis. Here, again, it is an excess of casts that should claim one's attention. They may be found after any violent exercise, in all fevers, in heart disease or anything else producing passive congestion, in senility, in the different varieties of anemia and leukemia, after the ingestion of all poisons, as well as in the three varieties of nephritis, although in Bright's disease they are usually more numerous than in other conditions. Any one of these causes may, likewise, account for the presence of albumin in the urine. The urea test is worthless, for the amount of this product in urine depends on the quantity of nitrogenous foods eaten, the digestion, absorption and the amount the individual normally retains. Equally worthless are the indican, phosphate, chlorid and uric acid tests.

If I could know but two things about a specimen of urine, I should ask for the twenty-four hour amount, and whether the greater part was passed during the day or night. One can easily inform himself, however, concerning the other points mentioned in the minimum examination. Never look for anything else, unless it be diacetic acid and acetone, and then only—save in cases of cyclic vomiting in children—if sugar be present. Personally, I never examine a sediment unless albumin is present.

No one questions the value in every case of examining such organs as heart and lungs. Many, however, will demur at the ears, and yet tophi have been found in them; the gums have been known to disclose lead poisoning; throat examinations, especially in very young children, often reveal diphtheria which might not otherwise be suspected until too late. Kidney palpation, it is said, will demonstrate 50 per cent. of all kidneys to be movable in the female, a condition to which innumerable symptoms are attributed, and in connection with which it is well to bear in mind the opinions of men of large experience, that it is not the movable kidney, rather is it the knowledge of its presence that accounts for symptoms; and, lastly, after systematic examination of each patient's arteries, no one of us will ever be guilty of the question, "Is arteriosclerosis often seen?" only to be told, "Yes: it is one of the commonest conditions we meet": for the arcus senilus, the hot feet of old persons and the burning hands of old washerwomen, the headaches, vertigos and hemiplegias of those past forty, angina pectoris, chronic interstitial nephritis, and the so-called visceral gout of the English are all manifestations of arteriosclerosis.

The examination which I propose requires from thirty to forty minutes time. If it were adopted and used intelligently, I do not hesitate to express my belief that it would supply us with more valuable information concerning the physical conditions of our patients than we are now generally obtaining. When we cease to commit the common sin of omission, we shall retain our patients instead of compelling them to seek aid of osteopath, so-called Christian scientist or other charlatan, to whom, be it said to our shame, many persons resort because the regular practitioner has not "made good."

A PLEA FOR THE PROMPT EVACUATION OF THE UTERUS IN THE TREATMENT OF ECLAMPSIA.*

HENRY D. FRY, M.D., Sc.D.
WASHINGTON, D. C.

In the whole range of obstetric practice, two diseases have claimed pre-eminently more victims and brought more sorrow into the human family than all others combined. They are sepsis and eclampsia.

For centuries a cloud of mystery obscured the causes of these two diseases. That of childbed fever baffled research until the brilliant observations of Semmelweis, and the later investigations of Pasteur revealed the cause and pointed out a line of treatment, both prophylactic and curative. Asepsis has almost eliminated puerperal infection, and the vigorous campaign waged against germs for the past half of a century has antagonized their virulence to such an extent that we seldom see now the destructive ravages of this disease. But what about eclampsia?

Zweifel has well said: "It is a disease of theories." About the time that Semmelweis made his fruitful observations regarding the cause and prevention of childbed fever Lever and Rayer demonstrated the presence of albuminuria in eclamptic patients. Frerich pointed out the close resemblance of eclampsia to the uremic convulsions of Bright's disease, and the attention of investigators was focused on the kidneys. The later destruction of theories founded on this line of investigation opened Pandora's box and a multiplicity of evil influences have been since evolved to explain the nature and causes of the disease. It is unnecessary even to enumerate these various theories, or, as they may be called, fancies. Passing over intermediate ground one comes to more recent studies and looks with encouragement of success to the theory of autointoxication. Intimately associated with fetal metabolism is the development of a toxemia in the pregnant woman. The nature of the poison and its source are yet unknown. The antagonism of healthy organs to the poison and its elimination from the system of the pregnant woman are important points for future study to elucidate. We believe that the effect of the poison is to produce certain visceral lesions, principally of the liver and kidneys, which, if unchecked, will pass beyond repair and lead to a fatal issue. Functional inactivity of the liver is the usual accompaniment of pregnancy. Hepatic involvement leading to degenerative changes, thrombosis of the perilobular veins and necrosis, further cripples the function of the liver. It is unequal to the task of disintoxication of the poison and a hepatic toxemia is induced.

---

* Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Eliminating fancies from consideration, I shall deal only with facts.

The essential facts bearing on the line of treatment advocated in this paper are these:

Eclampsia occurs before, during and after labor.

It may end fatally without the occurrence of convulsions; after one or a few convulsions only; or not until after a number of convulsions. It is admitted, however, that the maternal mortality increases progressively with the number of convulsions.

The termination of pregnancy, spontaneous or artificial, exerts a beneficial influence over the disease.

Death may occur before or after the termination of pregnancy.

Postmortem lesions are found principally in the liver, kidneys, heart and brain. Hemorrhagic foci and necrotic changes are demonstrated.

The termination of eclampsia in recovery or death depends largely on the progress of these visceral lesions. If the lesions have passed beyond the reparative stage before the termination of pregnancy, death will necessarily result. There is no way to determine the progress of these lesions. They may have passed the reparative stage before the onset of convulsions, but ordinarily this is not the case until after a number of convulsions have occurred. In evidence of this is the recovery of many eclamptic patients in spite of the fact that repeated convulsions had taken place. The danger line may be passed early or late in the toxemia. Having no means at our command of ascertaining when the lesions begin and to what extent they have progressed, the only safe rule to make is to terminate the pregnancy as soon as possible after the first convulsion.

Eliminate pregnancy and cut off the source of supply of the poison; then only is one in a position to eliminate successfully by treatment the poisonous agent or agents circulating in the woman's system. Her liver and thyroid gland may then be equal to the task of disintoxication, and her bowels, kidneys, skin and lungs to that of elimination.

On the other hand, most of the text-books of obstetrics and many obstetric writers give secondary importance to the obstetric treatment and primary importance to the general treatment of the toxemia. If labor pains have not begun they advise chloroform, morphin, chloral and veratrum viride to control the convulsions, and hot baths or hot packs, purgatives, salt solution, blood letting, etc., to eliminate the poison. Twenty-four hours, sometimes forty-eight hours or even longer are lost during which fresh toxin is being absorbed and pathologic visceral changes are progressing. These antepartum cases of eclampsia are the most serious with which we have to deal and give the highest mortality rate. We should take no chances in such a desperate condition, by attempting to eliminate a poison while the source of supply is allowed to go on. Treat a case of eclampsia just as you would a case of placenta prævia and recognize that the woman's safety depends on the immediate evacuation of the uterus. In one case you stop fetal metabolism, and in the other you stop hemorrhage. Having accomplished the evacuation of the uterus as soon as consistent with the safety of the woman, then, and not before, use your energies to eliminate from her system the poison that has already been absorbed. Consider the pathologic lesions that the poison is producing and save your patient's life, if possible, by emptying the uterus before these lesions have passed the reparative stage. Take nothing for granted. The progress of these visceral lesions is an unknown factor. Try to act on the safe side of the danger line, and to do this act at once. If your patient has had one convulsion do not wait for her to have two. Do not waste valuable time by eliminative treatment of the toxemia.

By this method the mortality of eclampsia will be reduced to its lowest figure. If, in spite of the prompt evacuation of the uterus, a fatal issue be the result, it is because of the early involvement and rapid progress of the visceral lesions. To save patients in this class of desperate cases one must wade up-stream and shut off the current of poison in the pre-eclamptic stage. This radical treatment is urged until we have a better method founded on better pathology. Future work may elucidate the nature and sources of the poison and point out a better line of treatment, but at present let us acknowledge our inefficiency and in the meantime save the lives of eclamptic women by terminating the pregnancy.

Besides the visceral lesions recognized as resulting primarily from the toxemia, postmortem examinations reveal secondary lesions in various organs due to complications which are liable to ensue. They are edema and congestion of the brain, apoplexy, edema of the larynx or lungs, pneumonia, nephritis, degeneration of the myocardium, etc. The frequency and extent of such secondary lesions bear a close relation to the number of convulsions that have occurred; therefore, another indication exists for the termination of pregnancy by prompt evacuation of the uterus, because that line of treatment is the quickest method of checking the recurrence of the convulsions.

In November, 1904, this method was adopted at Columbia Hospital and since then in my private practice. We can now report 15 cases of eclampsia and 1 of pre-eclamptic toxemia, with 1 maternal death. These cases were under the care of Drs. Moran, Sprigg, Roman, Kelly and myself.

The accompanying table shows these reports in abstract.

Thirteen of the cases were of primiparæ and 3 of multiparæ.

Ten were antepartum, 5 full term, and 1 not stated.

The number of convulsions that had occurred before artificial evacuation of the uterus was, respectively, 8, 16, 4, 7, 4, 3; not mentioned, 0, 2, 5, 3, 5, 1,1,1, 1. Twelve of the patients had no convulsions after the evacuation of the uterus; 2 had 2 each, and 2 had 1 each.

Three of the patients who had no postpartum convulsions were comatose for some time. One of these recovered after ten hours' coma; one developed puerperal mania and recovered, and one died after twelve hours' coma. In the fatal case (Dr. Kelly's, No. 7) the patient was abandoned by one physician; she was comatose when she came under the care of a second physician at noon Aug. 23, 1907, and when Dr. Kelly operated, without anesthesia, about 6 p. m. of the same day, she was practically moribund.

The methods employed to effect prompt delivery were: vaginal Cesarean section, in 12 cases; manual dilatation and forceps in 2; multiple incisions, manual dilatation and forceps in 1; symphyseotomy and forceps in 1. After vaginal Cesarean section, delivery was completed by podalic version or forceps. Patient 14 was a primipara who had a convulsion after fourteen hours of labor at full term. I saw her immediately after the convulsion and found a contracted pelvis (obstetric conjugate 3 inches). Symphyseotomy was performed and the infant delivered by forceps. There was no return of convulsions. Patient 8 was delivered by vaginal Cesarean section and podalic version on account of pre-eclamptic toxemia. In spite of active treatment, the gravity of the symptoms increased and the patient was on the verge of convulsions. She suffered from the usual symptoms of toxemia, had albuminuric retinitis, a large amount of albumin and casts with deficient kidney excretion. The report of this case is included in the table in order to give a full record of all the vaginal Cesarean sections that have been performed at Columbia Hospital. The vaginal Cesarean section, Case 8, was performed at my private hospital.

Statistics of eclampsia treated in public hospitals naturally give a worse result than those obtained from private sources. The uterus may be evacuated promptly in the sense of operating on the patients immediately after admission to the hospital, but unfortunately a large majority of these patients have been neglected and have had numerous convulsions before being brought to the institution. Only five of the fifteen patients tabulated, strictly speaking, can be said to have been delivered promptly; that is, they had had less than three convulsions. One of the patients had had 16 convulsions; one, 8; one, 7; three, 5; one, 4, and two, 3. In the fatal case (No. 7) the patient was almost moribund when admitted, and should not, in truth, be counted against the method. Patient 2 had had 16 convulsions and recovered. One maternal death in the 15 cases gives a mortality of 6.66 per cent. Cases 8 and 15 were treated in my private hospital, and, as they represent clearly the method of treatment advocated in this paper, I will report them briefly.

Case	Operator	Date	Age	Color	Para	Duration of Pregnancy Months	Number of Convulsions Before Delivery	Method of Delivery	Number of Convulsions After Delivery	Results	
										Mother	Child
1	Dr Moran	12/ 2 04	21	W	1	7	8	Vaginal Cesarean	None	Recovered	Lived a few hours
2	Dr Moran	12/25 04	22	C	1	7	16	Vaginal Cesarean	One	Admitted in eclampsia Recovered.	Premature. Lived six hours.
3	Dr Sprigg	3/ 6 '07	30	C	3	6½	4	Vaginal Cesarean	None	Admitted in eclampsia. Recovered.	Still birth.
4	Dr Sprigg	6/14 '07	24	W	1	9	7	Vaginal Cesarean	None, but very restless and comatose for longtime P. mania.	Admitted in labor. Recovered.	Lived.
5	Dr Sprigg	11/21 '07	23	W	1	7½	5	Vaginal Cesarean	None	Admitted in eclampsia but not in labor. Recovered.	Lived, although premature.
6	Dr Sprigg	10/30 '06	22	W	1	9	3	Multiple incision of cervix Manual dilatation and forceps.	Two	Admitted in labor. Recovered.	Still-birth.
7	Dr Kelly.	8/23 07	19		1	7¼	?	Vaginal Cesarean	No convulsions but never became conscious.	Comatose when admitted. Died.	Lived a few hours.
8	Dr. Fry	11/18 04	23	W	1	6½	0	Vaginal Cesarean	None	Pre-eclamptic toxemia. Placenta prævia. Recovered.	Lived 2 hours
9	Dr Fry	4/11 06	23	W	1	8½	2	Vaginal Cesarean	None	Admitted in labor. Recovered	Lived few hours
10	Dr. Fry	3/25 '07	16	C	1	?	5	Vaginal Cesarean	One (slight).	Admitted in eclampsia. Recovered.	Lived few hours.
11	Dr. Fry	11/ 9 '07	33	W	1	9	3	Vaginal Cesarean	None	Admitted in eclampsia. Recovered.	Lived.
12	Dr. Fry	12/11 '07	17	W	1	7	5	Vaginal Cesarean	Two	Admitted in eclampsia but not in labor. Recovered.	Lived 23 days; premature.
13	Dr Fry	1 4 08	32	W	1	7	1	Vaginal Cesarean	None	Recovered	Lived 3 months.
14	Dr. Fry	5 18 06	23	C	1	9	1	Contracted pelvis. Symphyseotomy and forceps.	None	Recovered	Still birth
15	Dr. Fry	12/ 3 '07	30	W	1	8½	1	Mid forceps after manual dilatation.	None, but comatose for 10 hours	Recovered	Lived
16	Dr. Roman	2 11 08	25	W	1	9	1 severe	Mid forceps after manual dilatation	None	Recovered	Lived.

CASE 8.—*Patient.*—Mrs. B., II para, aged 30. First pregnancy and labor normal.

Present Pregnancy.—Urinalysis during the second pregnancy was satisfactory until the eighth month of pregnancy, Nov. 22, 1907, when a large amount of albumin and a few hyaline casts were reported. The patient had taken a long automobile ride a few days before and the weather was decidedly chilly. November 25, she passed 88 ounces of urine with less albumin, specific gravity 1009, urea gr. 3 per ounce. November 27, urine was 108 oz.; albumin and specific gravity the same, urea gr. iv; November 28, 96 oz.; albumin 5 per cent. by volume, specific gravity 1008, urea gr. v; few hyaline casts. The patient entered my private hospital Nov. 28, 1907, and received active treatment. The large output of urine was due to slow colonic irrigation with normal salt solution. Her headache and nervous irritability increased and at 12:50 p. m. December 3, she had a convulsion.

Operation.—She was immediately carried to the operating room and chloroformed. The cervix was found to be effaced, the os softened and dilated to about the size of a silver half-dollar. Dilatation was completed manually and the infant delivered with forceps in seven minutes.

Postoperative History.—The patient was returned to bed and remained unconscious for ten hours. Her mind cleared up; there was no return of convulsions, and the urinalysis became normal after Dec. 27, 1907. The infant was about two weeks premature, weighed 6 lbs. 8 oz., and increased to 7 lbs. 4 oz. at the time of leaving the hospital.

CASE 15.—*Patient.*—Primipara, aged 32.

Pregnancy.—Last menstruation May 22, 1907. The patient passed a normal pregnancy and urinalysis was satisfactory until Dec. 29, 1907. On December 23 she passed 32 oz. of urine, specific gravity 1024; no albumin; urea gr. xiv per ounce, no casts. December 27, she noticed swelling of the ankles and had a headache in the morning. December 28, she had a severe headache all day; her face was swollen and she passed little urine. On December 29 I was called to see her at 10 o'clock at night, suffering, as she supposed, from "biliousness." She had severe headache, was vomiting, and her eyelids were edematous. A specimen of urine was obtained and it solidified by heat. Morphin was given hypodermically and a nurse was placed in charge of the case for the night. The next morning, December 30, the patient was brought to my hospital. The urine contained 75 per cent. albumin, hyalin and granular casts. The patient was treated actively by purgation with salts and given slow colonic irrigation with normal salt solution. Hypodermics of morphin were given p. r. n. to relieve her vomiting and restlessness and 15 grains of thyroid extract daily. She had a severe convulsion at 6 p. m. Jan. 4, 1908. In the meantime the condition of the urine showed improvement. The total quantity excreted was not ascertained December 31 and January 1, on account of the free purgation. Ten ounces on December 31 gave a specific gravity of 1020; 50 per cent. albumin; hyalin and granular casts. On Jan. 1, 1908, urine was 18 oz.; specific gravity, 1016; albumin, 25 per cent.; casts same; January 2, 48 oz.; specific gravity, 1018; albumin, 30 per cent.; urea gr., v; casts less. On January 3, for the twenty-four hours preceding the convulsion the patient passed 300 gr. of urea, and the amount of urine was 50 oz.; specific gravity, 1015; albumin, 40 per cent.; urea, 1 per cent.; casts same as previous examination.

Operation.—Immediately after the convulsion the patient was carried to the operating room and chloroformed. The cervix was not effaced; the os was closed. Vaginal Cesarean section was performed, with podalic version and forceps to the aftercoming head. Delivery occupied ten minutes; the operation was completed in thirty minutes and the patient put back in bed.

Postoperative History.—The patient recovered with no return of the convulsions. On the second day after the operation the urine amounted to 104 oz.; specific gravity, 1010; albumin, 10 per cent.; urea gr. ivss; few casts. From January 10 to 16, inclusive, there was only a trace of albumin and after January 18 it disappeared. There were no casts after January 20. On the seventh day after the operation the patient had a severe secondary hemorrhage from between the bladder and cervix. The cervical incision had been sewed with chromic catgut. The cavity was washed out with hot water and packed with sterile gauze. No further complications during convalescence. The infant weighed 3 lbs. 4 oz., was asphyxiated, but soon revived. It was placed in the incubator and fed by gavage. The infant seemed vigorous and was removed from the hospital when two months old. It died from an acute attack of indigestion when three months old. It weighed 5 lbs.

The mortality of the infants is high by this treatment of immediate delivery, but not more so than by pursuing a conservative line of action. The removal of the infant from its dangerous environment does not diminish its chances of survival any more than to leave it *in utero* subjected to the influences of maternal toxemia and to that of the eclamptic seizures. In these 16 cases the infants were premature in 10; full term, 5; not mentioned, 1. There were 3 still-births. Six infants lived only a few hours after birth; one, 23 days, and one, 3 months. Five of the 16 survived—a mortality of 69 per cent.

The mortality of the full-term infants was 40 per cent., and of the premature, 80 per cent.

It is only a fair inference to make that some of the infants that died could have been saved by more timely interference.

The number of cases of eclampsia which forms the basis of the conclusions arrived at in this paper is too small to formulate any rule if unsupported by the work of other investigators, but the lowest maternal mortality obtained by any method of treatment is by the immediate termination of pregnancy.

Liepman[1] says that the statistics of the clinics at Würzburg, Basel, Halle and Berlin give a mortality of 25 or 30 per cent. under expectant treatment and 2.8 or even 1.8 per cent. after immediate delivery. Zweifel[2] reports a mortality of 28.5 per cent. under expectant, and 11.25 per cent. under active treatment.

Glockner[3] gives the result of operative interference in 143 cases in the Leipsic clinic, with a maternal mortality of 15.49 per cent. At the Congress of Obstetrics and Gynecology, Paris, 1899, Ferri,[4] of Milan, reported 82 cases of eclampsia treated by artificial dilatation of the cervix, with a maternal mortality of 7 per cent.

According to the Bureau of Statistics of the Census Department, about 2,606,860 babies are born annually in the United States. Making due allowance for the usual proportion of plural births, this would represent 2,592,378 labors. Estimating one case of eclampsia to each 400 labors would give 6,480 cases of eclampsia every year. Under the expectant plan of treatment the mortality is placed at 25 per cent., and under prompt evacuation of the uterus. 10 per cent., a saving of 15 per cent. This means that by radical treatment, instead of the expectant. the lives of 972 mothers will be saved each year in the United States.

1900 Q Street N. W.

ABSTRACT OF DISCUSSION.

Dr. Laura House Branson, Iowa City: For the past four or five years I have been much interested in the study of syncytioma malignum; from that study I have concluded that a great deal of the toxemia of pregnancy is of fetal origin. Believing that, I advocate the view which Dr. Fry has promulgated, namely, that the uterus should be evacuated promptly and that no time should be lost in inducing labor in all cases of toxemia manifested by eclampsia. I advocate the prompt evacuation of the uterus in eclampsia, because of the high rate of mortality, the lives of both mother and child being in the greatest of danger in this disease, for which we possess no adequate means of treatment.

I advocate the evacuation of the uterus in primiparæ—and, in fact, in all patients—in whom convulsions occur before labor; I base this opinion on the summary of statistics at our disposal, among them those recently given by Partridge: in 1,577 cases of labor there were 56 cases of eclampsia, or 1 case of eclampsia in every 28 cases of labor; in 59 per cent. of these, convulsions occurred antepartum. Out of 33 antepartum cases in which labor was induced, convulsions ceased in 30. Sixty per cent. were primiparæ; average age, 27 years; maternal mortality, 30.3 per cent.; fetal mortality, 31.3.

Dr. William Mercer Sprigg, Washington: The result of the treatment outlined by Dr. Fry will give renewed hope to the country practitioner who may not be fortunate enough to have special hospital advantages. Dr. Fry has told us in his study of the cases that we have no means of knowing what the toxemia is or how great the toxic effect is going to be on the mother and child, and that it is important to empty the uterus promptly with the first eclamptic attack. If pregnancy has advanced to the term of viability of the child and there are positive symptoms of threatened eclampsia, I urge that the uterus be emptied promptly unless the symptoms subside within twenty-four hours or show marked improvement. We know that after the seventh month, or at seven and a half months, there is a good chance of saving the life of the fetus. The danger to the mother and child increase with the number of convulsions and by delay both lives are endangered. My own procedure in pre-eclamptic cases, when the mother was near term, and when symptoms did not promptly subside, has been to empty the uterus and I have never regretted doing so; but there have been times when I believe the uterus has been emptied too late and two lives lost in consequence. We must realize that as long as we do not know the poison we are dealing with it is our duty to give the mother and child every chance for their lives by emptying the uterus. Especially is this true in the light of our present lack of positive knowledge either in regard to the liver changes or the kind or amount of toxins circulating in the blood. If we wait for the eclamptic attack we are going to increase our mortality. Many of the patients in our hospital cases are sent in after they have had convulsions—one or two, as a rule more. As an illustration of the importance of not waiting for the convulsive seizure I would mention a patient that came into Columbia Hospital, Washington, D. C., about eight months ago for delivery. She was examined by the interne and a history of her case taken, which was negative. During the night she began to have headache; in the morning the urine was found to contain a small amount of albumin; specific gravity low; urea deficient. The headache continued to increase; there were flashes of light before the eyes, and in twenty-four hours the patient was almost totally blind. In thirty-six hours from the beginning of the symptoms the uterus was readily dilated (manually) under the influence of a small amount of chloroform. At no time was she completely anesthetized. Forceps were readily applied and a dead fetus delivered. The woman partially regained consciousness and died four hours later as a result of profound toxemia without having had a convulsion. This case illustrates the fact that we do not know when or how great these toxic changes are going to be. We must recognize this fact and follow the procedure which will give us the smallest mortality. The question of how this should best be done is of great importance. There are times when manual dilatation can be done with safety. If the symptoms of intoxication are slight and the uterus readily dilatable, you can take the time to dilate manually. If, however, the woman is a primipara and in convulsions, and the manual dilatation is difficult or impossible, and it is important to rapidly empty the uterus, and the child not too large to be delivered safely by the vagina, we have a procedure for this condition which is rapid and safe—that of vaginal Cesarean section. Professor Martin graphically described to you how easily vaginal section can be performed. It is an easy operation except in very fat women, and in such cases the operation is easy but the repair difficult.

Dr. H. J. Boldt, New York: We are all agreed that in these cases the uterus should be emptied as rapidly as possible. It is not a question of how many hours we are to wait before we interfere with the conception product, but it is a question of the severity of the eclamptic attacks. If the conditions are favorable there should be delivery by dilatation and version or the application of forceps. If, however, as Dr. Sprigg said, the condition is not favorable for that, we should pursue that course which gives us the quickest delivery, and that is vaginal Cesarean section. In still another class of cases there are seizures subsequent to the delivery of the child. Up to a comparatively short time I have held myself aloof from endeavoring to see what can be done by the decapsulation of the kidneys strongly advocated by our confrère, Dr. Edebohls. The reports from this procedure are coming in more and more from all civilized parts of the world. I believe, therefore, that as conscientious men and as investigators we should not be partisan, but when the necessity seems present make use of procedure which has, in other hands, proved lifesaving.

Dr. R. S. Yarros, Chicago: Until we know the exact cause of eclampsia we can know very little about the medical treatment of it, and it certainly seems that the best results follow from a prompt evacuation of the uterus. Even the infant mortality is greater than when radical treatment is postponed, as is illustrated in public hospital practice, where patients are taken, usually after hours of delay and more or less expectant treatment by some outside physician. In my own private practice I recall a patient who at the end of her fourth pregnancy had symptoms of threatened eclampsia, was treated by the expectant method for three days, when the child was born naturally. About twelve hours after delivery the child had two convulsions and died. The next pregnancy of the same patient was perfectly normal until four hours after the onset of labor pains, when she had a typical eclamptic convulsion. Before I had time to prepare myself for immediate delivery she delivered herself. That child, too, had a slight convulsion, and some albumin was found in the urine, but under proper treatment recovered. Let me in this connection add that we frequently forget that the children born of eclamptic mothers are in a toxic condition and should be treated as such.

Dr. Bernard Cohen, Buffalo: Dr. Fry did not touch on one of the principal things to do with the pregnant woman. If the physician or obstetrician gets a chance to educate the women who come to him early, many of these cases of eclampsia will not occur. The obstetrician usually finds the woman with a convulsion. In the smaller country towns this is just as likely to occur as in the cities. I want to persuade those who live in the small towns, if they are not fully equipped with the instruments needed or familiar with the technic of vaginal Cesarean section, to become acquainted with the original Sänger operation. If the patient's condition in a case of eclampsia is good, advise that the physician dilate with the fingers and empty the uterus after the methods of Harris and Edgar. Let him do it the way he knows he can do it, but let the uterus be emptied. Those who see the pathologic results of eclampsia, the brown, necrotic condition of the liver, know the importance of this. I have seen many a time the postmortem specimens of the kidney in which there was not the slightest lesion. In numerous cases seen by Ewing the liver was broken down with necrotic foci, and in only a few of the cases were the kidneys in a pathologic condition. The poison is immediately sent from the liver to the brain and if you allow a woman to have convulsions for any length of time it leaves some lesion. The child should not be allowed to nurse from an eclamptic mother for at least three weeks.

Dr. J. H. Carstens, Detroit: The point made by Dr. Cohen about having the woman attended to before confinement is good. You can prevent cases of puerperal convulsions by bringing on labor. There are various methods besides operation, and there is no reason why we should not make use of those at the present time. In the hospitals we use manual dilatation. We can use the Bossi dilator and various other methods to evacuate the uterus quickly—the vaginal Cesarean section, so-called, or another Cesarean section. What I plead for is that the general practitioner familiarize himself with the method of doing this operation. He can do it if he will simply go to work at it, and it is our duty to teach the general practitioner how to do it. He can get somebody to help him, and the danger of vaginal Cesarean section is so small and the results so very good that every one ought to be prepared to do it. The patient is going to be dead in an hour or two unless something is done and you have got to save her just then.

Prof. August Martin, Berlin: If eclampsia is a symptom of infection we must be careful not to add to this infectious poison. It is still to be determined what kind of an infection it is. It is generally believed to be a poison developed in the ovum. I do not so regard it, because we know that eclampsia has been observed in cases of very early pregnancy in which there was no fetus, in cases of degeneration of the ovum. Evacuation of the uterus must be done as soon as possible, when the uterus is preparing for the expulsion by stretching the uterus, or if this is not going on then by opening the uterus by vaginal Cesarean section. I believe that in most instances thereby the danger can be avoided. Nothing has been said as to prophylaxis. I think that this important matter should attract the utmost attention of the general practitioner. We frequently hear that the patient has felt all right. She may have had a little headache or felt rather tired and then like a thunderstorm the disease sets in. If you study these cases more intimately you will find that this is not the way the disease develops. In many instances these patients have long suffered from severe headache in front and behind and loss of appetite. They feel rather uncomfortable and very not been uniformly good by any means, probably on account of the well-known shortcomings of these sera, and the fact that the strain of streptococcus causing the complication was different from that used in the production of the serum. In other words, the sera used were not specific.

Much more valuable evidence has recently been brought forward in the use of homologous vaccines, and the study of the opsonic index in relation to the several secondary organisms found in the sputum. Marked improvement has been reported by several authors following, and apparently in consequence of, the administration of bacterial vaccines made from the organisms of the patients' sputum. These results can be explained only on the ground that these bacteria were active invaders, acting injuriously on the host. Improvement was brought about by increasing the opsonins in the blood. As this action is specific we are amply justified in holding that these secondary bacteria took an active part in the evolution of the disease, and the causation of symptoms.

CONCLUSIONS.

While we have much to learn concerning the rôle played by mixed infections in pulmonary tuberculosis, the evidence seems to justify the conclusion that such infections modify the course of the disease injuriously, being the causative factors in some of the great accidents, or aiding in their production, and tending generally to shorten life. In many cases they appear to be the direct and immediate cause of death.

AIR INFECTION OF MINOR IMPORTANCE.*

CHARLES V. CHAPIN, M.D.
Superintendent of Health.
PROVIDENCE, R. I.

BASES FOR THEORY OF AIR CONVEYANCE OF DISEASE.

When it becomes necessary to question long-established beliefs, we are less likely to be disturbed if we first ascertain what were the original grounds for those beliefs. As long as scientific medicine has existed, infectious diseases have been thought to be air-borne. Whenever it was recognized that any disease was infectious, an effort would be made to explain how persons distant from the source of infection could acquire the disease. The most obvious explanation was that the *materies morbi* were wafted by the air. This served to explain fairly well the phenomena of epidemics and of localized outbreaks and the occurrence of single cases of infection. In one common disease the clinical evidence of the important part played by the air was very strong. Malaria has prevailed extensively throughout the civilized world since the dawn of history, and the evidence that the virus of this disease is air-borne is so clear that it amounts to a demonstration, so that it was but natural that what was proved for one infectious disease, and that disease the one with which men were most familiar, should be assumed to be true of all others. In a sense malaria is air-borne: its germs are carried in the bodies of mosquitoes; but it is the insects, rather than the germs, that are carried by the air. Unless the parasites of the other common contagious diseases are carried by similar feeble-winged insects, we can draw no argument as to their mode of transmission from what is known of malaria. It is perhaps here necessary to say that this paper does not deal with such diseases.

The location of the initial lesion in some diseases has helped the theory. The mouth is infected in mumps and diphtheria, the lungs in tuberculosis and pneumonia, and it is easy to believe that germs in the inspired air are their cause. At one time pathologists maintained that examination of the tissues yielded positive evidence that the lungs were usually the site of the primary lesion in pulmonary tuberculosis and that this indicated that the disease was air-borne. Many, however, dissent from this opinion. The subject is a difficult one, but it can hardly be said that the facts of pathology prove that tuberculosis is in most cases an air-borne disease.

I suppose, however, that the chief reason why the theory of aerial transmission has been so generally accepted is that it afforded the best, or perhaps the only, explanation of the facts of infection. When cases of infectious diseases develop at about the same time in a neighborhood, or one after another without any apparent connection, or when isolated cases continue to appear from time to time, scattered over a city, the question arises how are they caused. There is no apparent communication between them. The most natural explanation is that the infection is carried by the air. Another explanation is that infected articles have borne the disease from the sick to the well. These two possible modes of transmission, by the air and by fomites, were about the only ways we had of explaining the vagaries of the distribution of the contagious diseases. If we have another and better explanation we should discard the older theories, or give them a minor place.

It is only within a dozen years that we have begun to realize that pathogenic organisms are by no means confined to those who are sick. Bacteriology has shown us that mild unrecognized cases are much more common than had been supposed, and that persons infected, but showing no symptoms, that is, "carriers," are still more numerous. There are enough of these mild cases and carrier cases to maintain the contagious diseases by direct contact. The demonstration of this can not be undertaken here, but it must be admitted by all who study the problem. Such a source is proved for some cases. Why not assume it for most cases, rather than assume aerial transmission? If one does not recognize the existence of these numerous carriers he will take little interest in this paper, and will cling to what seems the necessary theory of aerial convection. If he does recognize the importance of carriers he will no longer consider the former theory necessary and ought not to hold to it unless actual evidence of its truth can be adduced. Let us see then what evidence there is in favor of the notion that diseases are usually air-borne, and in the first place let us inquire what is the probable mechanism of the transmission of disease germs through the air.

EVIDENCE OF TRANSMISSION.

To those who believed in the aerial transmission of disease, the announcement that bacteria are not readily detached from moist surfaces came as a great surprise. It was a serious blow to all our time-honored ideas to learn that the expired air is free from germs, for no notion was more firmly fixed than that the breath of the patient filled the room and the house with infection. Yet the demonstration was conclusive that bacteria are not spontaneously given off from moist surfaces, but, on the contrary, are easily entangled on such surfaces, so that the microbes of the inspired air are made prisoners on the mucous membrane of the air passages, and the expired air is free from all infection.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Other modes, however, were soon suggested by which bacteria might get into the atmosphere. Not only are bacteria not detached from moist surfaces, but they are not detached even by powerful air currents from firm dry material, unless the latter is mechanically disturbed. This is particularly true of the secretions and excretions of the body, which when dried present a somewhat firm glazed surface. But it was soon suggested that this dried infective material, be it sputum, saliva or feces, might become pulverized, and that then the light particles, containing living bacteria, would be easily carried by air currents. The question of dust infection then became a vital one. The problem as to whether such dust can and does cause disease may be studied in various ways.

In the first place, it is important to know whether bacteria on drying retain their virulence. Evidence on this point is voluminous, but conflicting and difficult to analyze. Spores, of course, retain their virulence, but it is worthy of note that our most common spore-bearing pathogenic organism, namely, that of anthrax, appears not to be air-borne, that industrial anthrax is rarely of respiratory origin, but that the initial lesion is in a large proportion of cases on the exposed skin and is probably due to contact infection. Of the non-spore-forming bacteria many, such as the pneumococcus, the gonococcus, the meningococcus, and the influenza bacillus, have so little resisting power that dust infection appears to be impossible. Other germs, like those of typhoid fever, tuberculosis and diphtheria, may resist drying, and there is no theoretical reason why they might not at times be air-borne.

The next point for investigation is whether pathogenic bacteria can actually be found in the air. Although this subject is extremely important, the search is a difficult one, and not a great deal of reliable work has been done. There is little doubt that the pus organisms are the most ubiquitous of all disease germs, and they have been found in the air in many situations, including the streets, hospital wards and operating rooms. Virulent tubercle bacilli also have been found in the air, though, as might have been expected, many negative examinations have been reported.

Much more numerous are the experiments which have been made to discover disease germs in dust, particularly tubercle bacilli. The work of Cornet, Coates and others has amply demonstrated that in the vicinity of tuberculous patients, especially if careless, infected dust may be found.

The bacteriologic evidence is that no germs have been found in the air except those of suppuration and tuberculosis, and careful experimental investigation of the subject indicates that few disease germs are capable of being carried as dust and remaining virulent.

The doubt cast on the theory of dust infection led to further studies. Flügge showed that in coughing, loud talking and even in ordinary speech, minute droplets of saliva are given off which are infective. Animal experiment has, however, shown that they are not effective at a distance of more than two or three feet.

We ought now to ask what experimental evidence we have that either air-borne dust or droplets are actually infective under ordinary natural conditions. It must be confessed that the evidence is rather scanty. A number of crude experiments are on record in which large quantities of dried and pulverized material containing the germs of tuberculosis, plague, Malta fever, and anthrax have been forcibly blown into the nostrils of test animals with fatal results. Cornet confined forty-eight guinea-pigs in a compartment in which dust containing tubercle bacilli was vigorously stirred up, and nearly every one of the animals developed the disease. The conditions, however, were far from natural. Flügge had no difficulty in infecting guinea-pigs by keeping them in front of a patient distant from 20 to 45 cm. for a short time, and allowing the patient to cough at them. Even under ordinary conditions of speaking such infection takes place. The U. S. Department of Agriculture has investigated the mode of tuberculosis infection in animals. In one experiment two healthy cows were kept in stalls between tuberculous animals, and both became infected without actual contact; ninety-eight guinea-pigs were kept in cages in the stalls, and some under the mangers of tuberculous cattle, for about six months, and only one of the pigs (kept under the manger) became infected. In a later experiment, of thirty-five guinea-pigs exposed in cages on the walls of stalls where tuberculous cattle were confined, only two became infected after an average exposure of 135 days. Of forty-two guinea-pigs exposed under the mangers, so that some of the feed sifted into the cages, six were infected. In the last experiment the disease is more likely to have been caused by contact infection than by air infection, but in the other cases the disease may have been air-borne, but unless scrupulous care was used by the attendants during the six months, it was likely due to contact infection.

The British Plague Commission reports some interesting experiments with that disease. Susceptible guinea-pigs and monkeys were confined in cages placed in infected huts, and also near infected animals, but they did not in any instance acquire the disease so long as precautions were taken to exclude fleas. These experiments were well conducted and indicate that plague is not an air-borne disease in the ordinary meaning of the term.

Except for the above diseases very few experiments have been made on aerial transmission.

We must next inquire what clinical evidence we have that the air is a factor in the transmission of infectious disease. It was formerly believed that not only was the air of the sick-room infected, but the disease poison was carried out of the house and long distances in the open air. This view has been gradually abandoned for one disease after another, until at present smallpox alone is believed to spread in this manner, and many epidemiologists deny even this.

When influenza reappeared in 1889, extending over the entire globe in a few months, there were many who contended that this phenomenon could be explained only on the theory of its aerial transmission, and even maintained that it was thus borne across the Atlantic; but the researches of Parsons in England and Schmid in Switzerland showed conclusively how necessary personal intercourse was to the development of the disease.

It is for the aerial convection of smallpox, however, that we find the greatest weight of authority. Investigations made by Dr. Power for the local government board in England in 1881, concerning the Fulham Hospital, convinced the authorities that smallpox hospitals are a serious menace to their neighborhood, and they advised that such hospitals should, if possible, be located a mile or more from inhabited houses. Many local health officers agree with these conclusions, but many do not. The subject is too intricate to discuss here, but the believers in aerial convection base the theory almost exclusively on the alleged fact that smallpox in a great number of instances prevails in excessive amount around the hospitals, and with a progressively decreasing intensity as distance from the hospital increases. Such facts, they say, can be explained only on the theory of aerial convection. That such a distribution of cases commonly occurs is denied by many, and when it does occur it has sometimes, as in recent outbreaks in England, been shown to be due to contact infection.

If smallpox virus is powerful enough to infect at the distance of a mile, it ought certainly to infect every susceptible person in the same room or within a hundred feet, and this is notoriously not the case. The belief that smallpox is air-borne to any distance is contrary to the facts, at least as observed in this country.

It has also been alleged that typhoid outbreaks are sometimes due to air-borne infection. But in all the recorded instances which I have examined there is not the slightest evidence that the disease originated in the manner alleged.

Assertions are made even now by some that other diseases are carried by the external air. In Paris the question has been raised of the possibility of scarlet fever spreading from the hospitals, but Tarnarier has shown by a statistical study that there is no evidence of it. In American cities also assertions are sometimes made that scarlet fever and diphtheria are carried by the air from hospital wards to adjoining wards or neighboring houses. In no instance in which such transfer has been alleged has transfer by carriers been excluded. Moreover, many contagious hospitals have been maintained for years with no increase in these diseases in the vicinity, as, for instance, at Boston and Providence. At the Kingston Avenue Hospital in Brooklyn various diseases, as smallpox, measles, scarlet fever and diphtheria, are treated in wards only a few feet apart, with no evidence of aerial transference. At North Brother Island the tuberculosis ward is only about twenty-five feet from the diphtheria ward, but Dr. Knopf tells me that his tuberculous patients do not contract diphtheria.

While the majority of the medical profession do not believe that diseases are carried by the outer air, they do believe that most patients with tuberculosis, smallpox, diphtheria, scarlet fever, measles and whooping cough contract the disease by breathing the germs.

It is commonly believed that the germs of disease readily pass from one room to another in a dwelling and a carbolized sheet before the door is often hung up by physicians and health officers to prevent the extension of the disease. But the facts are that even with entire disregard of the ordinary rules of cleanliness in the sick-room, the disease rarely extends beyond the apartments occupied by the patient. Careful records kept in Providence for many years show that, in both scarlet fever and diphtheria, the disease is confined to the tenement in which it first appears in about 93 per cent. of the houses, and in nearly all of the instances in which it does attack more than one family in the house, there is known to have been direct communication between the families. If there is no visiting between the families the disease never spreads. This demonstrates not only that scarlet fever and diphtheria are not air-borne, but also that, although members of the infected family may use hallways, stairs, cellars and water-closets in common with other tenants, the danger of infecting the latter may be safely ignored.

It very frequently happens that persons infected with scarlet fever, diphtheria or smallpox remain for days in schools, asylums, or lodging houses, and yet infect few or none. Such a phenomenon seems to be more easily explained if infection takes place chiefly by contact, rather than through the air, and certainly indicates that aerial infection is not so swift and sure as is usually supposed.

Visitors to wards occupied by scarlet fever and diphtheria patients rarely contract these diseases. Welsh and Schaumberg state that of 700 medical students who visited the scarlet-fever wards of the Philadelphia Hospital, not one contracted the disease, although fully one-half the number had never had it. In a personal letter Dr. Schaumberg states that about the same number visited the diphtheria wards with a like negative result. The stay in the wards was from twenty minutes to an hour and the visitors were not supposed to touch anything without washing the hands.

The best experiment on the mode of infection seems to have been made recently in some of the French hospitals, particularly the Pasteur Hospital in Paris. In this hospital each patient is cared for in a separate room opening into a common hall. Different diseases may be in adjoining rooms. The doors are, of course, frequently opened and are often left open. The same nurse may care for patients with several diseases. The nurses are trained to take the same care in going from one case to another that they would in going to a surgical operation. In fact, strict medical asepsis is the watchword of the institution. To treat smallpox in a room opening into a corridor connecting with the rooms of scarlet fever and diphtheria patients, would by most persons be considered the height of folly, but at this hospital during the two and one-half years after it was opened in 1900, there were received 2,000 persons, of whom 524 had smallpox, 443 diphtheria, 126 measles, 163 erysipelas, 92 scarlet fever and 166 non-diphtheritic sore throats. The only evidence of the transfer of infection was the development of four cases of smallpox and two of erysipelas.

At the childrens' hospital in Paris (*Hôpital des Enfants Malades*) instead of being in separate rooms, the beds are separated by partitions. The same asepsis is prescribed as at the Pasteur Hospital, but does not appear to be as carefully carried out. There are treated in these wards all kinds of contagious diseases, including typhoid fever and pneumonia. Of 5,017 cases there were only 7 cross-infections, 6 of measles and 1 of diphtheria. Dr. Moizard thinks that this experience proves that even measles is not air-borne. The cases of this disease which did arise were not in cubicles adjoining those occupied by measles patients.

Dr. Grancher, in another Paris hospital, had two wards in which there were no partitions, but only wire screens around the beds, simply as a reminder for the nurses. He also attempted medical asepsis, but as the period covered was from 1890 to 1900, the details were doubtless not so well understood or applied. Doubtless, too, the permanent partitions have a moral effect on the minds of the attendants. Of 6,541 patients treated during this period 115 contracted measles, 7 scarlet fever and 1 diphtheria. This is a much larger rate of infection than that shown for the other hospitals, but not as great as in many hospitals with separate wards for each disease. Grancher insists that measles is probably not an air-borne disease. Adjacent patients do not necessarily infect one another. At various English hospitals similar methods have been tried with success. These various hospital experiences indicate that the danger of the aerial convection of disease is much less than is generally supposed.

The history of surgical practice is interesting in this connection. Lister at first believed the air to be the principal source of infection. Gradually surgeons came to consider the organisms of suppuration on their hands, instruments and dressings, and on the skin of the patient as the principal source of infection, and I think that I am not wrong in saying that at the present time surgeons have little fear of aerial infection. Ochsner says that it is a negligible factor. Yet the pus-forming organisms are probably more numerous in the air than any other pathogenic bacteria.

CONCLUSIONS.

After the foregoing survey of the subject we are, I think, justified in the following conclusions:

1. The theory of the aerial transmission of disease was developed as the most reasonable way of explaining the phenomena of infection.
2. Contact infection with carriers and missed cases affords a better explanation of the phenomena.
3. The best medical thought has been steadily restricting the supposed sphere of aerial transmission.
4. Only a few authorities now assert that disease is carried by the atmosphere outside of dwellings, and this assertion is made only with regard to smallpox.
5. Bacteriology teaches that former ideas in regard to the manner in which diseases may be air-borne are entirely erroneous; that most diseases are not likely to be dust-borne, and they are spray-borne only for two or three feet, a phenomenon which after all resembles contact infection more than it does aerial infection as ordinarily understood. Tuberculosis is more likely to be air-borne than is any other common disease.
6. Animal experimentation indicates that tuberculosis may be air-borne, and that plague and some other diseases are not.
7. Pathology has not determined, as is sometimes alleged, that even pulmonary consumption is an air-borne disease.
8. There is no good clinical evidence that the common diseases are air-borne.
9. There is considerable clinical evidence that scarlet fever, diphtheria, smallpox, measles, whooping cough, typhoid fever and plague are not easily transmissible through the air.

If these conclusions are correct, are we not justified in abandoning the theory of aerial transmission as a working hypothesis, and should we not devote ourselves to preventing every form of contact infection? To use the phrase of the French physicians, we should, in our treatment of contagious diseases, practice strict medical asepsis. This I have learned by experience we can never teach people to do so long as they continue to believe that air is the chief vehicle of infection. That there is little danger in neglecting the aerial factor is indicated by hospital experiences of Paris and other cities.

UNIFORMITY OF VITAL STATISTICS.*

J. N. HURTY, M.D.

INDIANAPOLIS.

A large percentage of the people who call at the statistical department of the Indiana State Board of Health ask: "Of what practical use are vital statistics?" This question proceeds as frequently from doctors as from the laity. It is from doctors also that we continually receive letters protesting against the inconvenience of making reports of the deaths and births they attend. Frequently, to tell such persons that the collection of accurate vital statistics and their intelligent analysis constitute one of the most important functions of governments is to talk into the air. The results are sometimes discouraging when the subject is continued and it is made plain how vital statistics give a valuable measure of the advance in medicine and of the results of the practical application of hygiene. Without vital statistics, practical hygiene is a good ship at sea lacking a compass, and it is true that it is far more important for a state to know who are dead, where they died, and what caused death, than to know the number of hogs, bushels of corn and acreage of oats. Still, these truths, obvious as they are, remain invisible to many.

MEDICAL PROFESSION RESPONSIBLE.

On the medical profession devolves the responsibility of giving to the world accurate mortality, morbidity and birth statistics. This is really an opportunity which conditions bring to the medical profession, for such records are of great importance to medical science; and where is the true disciple of medicine who will not gladly contribute to the science he has made his life study? Again, it is clear that a physician's duties to his patients and their families are not all performed until the records which are so important to them and which the physician only can make are duly returned. Birth and death records, therefore, are far from being solely for the benefit of the state. Indeed, their value to the state is not primary. To summarize them we may say: Birth, mortality and morbidity records are of very great importance to medical science, to the family and to the state. Medical colleges should provide a special course of instruction concerning the collecting, classifying, tabulating and analyzing of vital statistics. Medical students should be taught the importance of recorded life data: 1, to the individual; 2, to the profession of medicine; 3, to the general public; 4, to sociologic problems; 5, to public hygiene.

In connection with their duties in regard to reporting deaths, medical students should be especially and thoroughly instructed in precision in statement of causes of death, necessity for complete returns and the relation of sex, age, color, race, conjugal condition, parents, nativity and occupation. Examining medical boards should examine applicants to practice medicine in the general subject of vital statistics.

UNIFORM REGISTRATION METHODS.

It is plain that, unless the vital statistics of different states are compared with each other, not a little of their value will be lost. To this end, and also to the end that gain all along the line should be secured, uniform registration methods for vital statistics should exist. But, how may they be secured? The United States Bureau of the Census three decades ago urged that the states should have registration laws furnishing correct and comparable vital statistics, yet, at this date, only *twelve* states have such laws. The bureau has issued and distributed ten or more circulars relating to registration, and one, entitled "Legislative Requirements for Registration of Vital Statistics," gives clearly the essential principles which should be incorporated in all laws to make them effective in the work.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

The first and absolutely necessary requirement in a mortality registration law is a burial permit issued by a sworn registrar, the said permit to be based on a standard certificate of death, intelligently and as completely filled out as possible. And here lies the greatest difficulty, for in Indiana, after eight years of daily prodding from the office of the State Board of Health, at an expense for a special clerk and for untold postage stamps, the number of indefinite terms used has not decreased. There seems to be a decided reluctance on the part of some physicians to be accurate and definite in their statements of causes of death. He who invented such terms as marasmus, kidney complaint, liver trouble, nervous shock, etc., did not have in mind accuracy, definiteness and other needs of mortality statistics. And what about the returns from those practitioners, not few in number, who certify scarlet fever, diphtheria and cancer deaths as being caused by "malignant diseases"? What of those who call diphtheria "ulcerative tonsillitis," and who return for intestinal tuberculosis the term "chronic diarrhea"?

The difficulties to be overcome in securing the reporting of all deaths is not so great as that of banishing incorrect and indefinite terms. A registration law which does not require deaths to be recorded immediately after their occurrence with definite causes of death stated in acceptable terms and which does not deny legal burial until the same is done, is entirely worthless. The further the time and place of record are removed from the time and place of the occurrence, the greater is the probability of non-registration and the greater the possibility of error in giving the statistical and medical facts. Appreciating these truths, the Indiana law commands immediate report of death on an official certificate, and before legal burial can be made a burial permit based on said certificate must be issued. In this it is not different from other efficient registration laws, but in the penalty for burial without a permit it is very different. Besides a fine of from ten to one hundred dollars for illegal burial, which penalty it is impossible to have imposed in certain pathetic instances, the Indiana law commands the coroner under penalty for failure, and with a reward for compliance, to disinter the body, hold an inquest and make a return of his findings on regulation death certificates, and to further the using of definite terms of causes of death, the back of the certificate contains a list of three dozen terms which can not be accepted. Then the careless or ignorant physician has always at hand information which will guide him aright.

The first necessity of immediate report on official blanks and a burial permit being met, then follows the necessity of an immediate local recording and the transmission, at least monthly, of the original certificate or transcript to a central authority, where, under a trained statistician, classification, tabulation and analysis can be done. To secure this, the law should command it be done under penalty, and the central board given power to pass rules and regulations, the violation of which would result in the discharge of the offender with a fine.

A UNIFORM CERTIFICATE OF DEATH.

The adoption of the same form of death certificates, or at least essentially the same form, by all registration authorities is necessary. So likewise is the adoption of the same method of classification. Fortunately, both forms have been ably supplied, the certificate form by the United States Census Bureau and the classification system by the International Congress of Hygiene and Demography.

Experience has shown, however, that the certificates can be improved, and so the Indiana State Board of Health has made a few changes in the United States form. The United States certificate, under "personal and statistical particulars," calls for the birthplace of the deceased, but simply has the word "birthplace," followed by a blank; and, although it is plain that the birthplace of the deceased is wanted, still constant inquiries were received asking as to this point. The same situation appeared as to occupation. So the Indiana certificate now has "birthplace of deceased" and "occupation of deceased" printed on it. It also has printed on the back a list of the most common indefinite terms used in stating causes of deaths, thus presenting suggestions to those filling the blanks.

EFFICIENT LOCAL REGISTRARS NECESSARY.

A good law, even though constructed on the given principles, will not enforce itself; and, therefore, efficient local registrars are a necessity. These should exist in every city, town, county and township. In Indiana, registrars are to be found wherever a coffin can be purchased. They should be intelligent and thoroughly informed in regard to their duties, and impressed with the great importance and usefulness of vital statistics. They should know and feel that the seemingly trivial act of collecting, recording and transmitting of death certificates is a matter of importance to medical science and to the state, and possibly of great importance in the future to the family of the decedent. For the state to fail to pay registrars properly is to encourage inefficiency; and this is all too frequently done. It seems that the best basis of payment would be a sufficient fee for each certificate handled. Of course, the responsibility for obtaining and filing the original certificate of death with the registrar should be fixed in the law. But on whom? He who buries the body must be the holder of the burial permit, just as he who pays out money should hold the receipt. The undertaker is, therefore, the one who should be required to deliver the certificate of death, and said certificate should be readily supplied by the attending physician, if any, otherwise by the local health officer or coroner. In case there is no undertaker, and the family with the help of the neighbors conduct the burial, then the head of the family or the chief actor in the case must hold the burial permit; and he must bear the certificate to the registrar. With all of this system duly and legally provided, the people must be informed and registrars must be diligent and conscientious in the discharge of their duties and must have the cooperation of the medical fraternity and the people. The securing of this cooperation will, of course, depend on the statistical department; and that persistent, unceasing labor and enthusiasm and much tact will be required to accomplish this end is very plainly apparent.

BIRTHS.

The securing of records of all births is obviously more difficult than the securing of records of all deaths, and in neither instance can absolute accuracy be secured. The Laporte Gunness horror reminds us that concealed deaths are continually occurring, only not in groups, and when not discovered are lost. So, also, births are continually occurring in remote places, which, on account of ignorance and stupidity, are not reported, and even in cities this occurs with the additional fact that many are purposely concealed. Therefore, we are concerned only with such records as can be secured by the exercise of diligence.

Births should be immediately reported. The courts would probably interpret "immediately," as meaning within twenty-four hours. It is unnecessary to give longer time. To do so in many instances brings inaccuracy, and in not a few, failure to report at all. The ten-day period allowed in the bill of the Committee on Uniform Vital Statistics should, in my judgment, be changed to one day.

The experience of the Indiana State Board of Health shows it to be desirable to have the postoffice address of the mother, and this item has been added to the blank. It is the mother to whom we must usually appeal for the name of the child. She has the deepest interest, and she will almost always answer a letter asking for the name. If the birth is in the country in Indiana, the postoffice address would not be given on the blank of the United States Census Bureau; only the township would be given, and there might be two, three or more postoffices in that township. We have also found it necessary to add county, township and village or city as well as postoffice address to the supplemental blank. These do not occur on the United States blank.

Another addition, which is made for purely sanitary and not statistical reasons has been made to the Indiana birth blank. It is: "Were precautions taken against ophthalmia neonatorum?" We believe that this question has produced good results, for letters have been received asking what precautions the State Board of Health recommends, and one county medical society has taken up the matter and appointed a member to write on the subject. The presence of such a question on a birth certificate could be properly criticized from the statistical point of view, but if it advances preventive medicine and does good it seems to be justified.

In writing to the mother for the given name we use the following form of letter, with which is enclosed the supplemental blank, all filled out, except the name, and also a stamped return envelope.

> *Dear Madam*:—We have received in this office for legal record, the birth certificate of your baby. Please fill out the enclosed blank where child's name is called for and return to us in the stamped and addressed envelope, and please correct any errors, either in dates or spelling of the names.
>
> This legal record of the birth and name of your child is of great importance to you, to your child, and to the state. Some day it may be required in court to prove your child's parentage, or to prove inheritance of property, or to prove right to insurance or pension, or to prove legitimacy. Every mother should demand that her child's birth be legally recorded as the law commands, and also demand that the physician or midwife carefully look after the matter, for their duties are not fulfilled and they should not be paid for their services until they make the report required by law. Women will do wisely to discuss with each other the importance to themselves and to their children of legal records of births and deaths.
>
> If at any time the State Board of Health can help you, please write to us.

We are glad to be able to say that only occasionally do we fail to hear from this letter. We find also that the letter has the missionary effect intended, for we have heard of many instances in which country women have talked about the necessity of recording deaths and births, and several women's societies have formally discussed the subject. The sending of this letter also presents the opportunity of sending, without additional cost, a leaflet concerning the care of babies.

ABSTRACT OF DISCUSSION.

Dr. Cressy L. Wilbur, Washington, D. C.: Dr. Hurty, I think, referred to the twelve registration states. We are doing a little better than that. There are fifteen registration states at present, not counting the District of Columbia (city of Washington), which formerly was included in the list of registration states. There has been a break in the continuity of registration from the east to the west, but Ohio has bridged that gap, and under a law signed by Governor Harris on May 4, Ohio will undoubtedly soon become a registration state. I have good news also to report from the northwest. Wisconsin, Minnesota, North Dakota, Montana, Washington, Nebraska and Utah all have laws in operation requiring burial permits, and it only requires full enforcement of these laws to secure the addition of these states to the registration area. I am sorry to say that at the present time—and there are a great many people living in this great city of Chicago who would hardly credit the statement—Illinois is a non-registration state. Illinois, as a state, does not have an adequate system of vital statistics. I am glad that the state sanitary authorities and the city health departments are interested, wide-awake and willing to cooperate in this matter, and I believe that we shall have a good registration law at the next session of the legislature. At Washington we receive returns from all registration states and cities, and there is no city in the Union which sends better reports or where the causes of death are more carefully investigated than in Chicago. The work now being done in this city should be of great aid in securing the enactment of a law for the entire state.

Dr. J. A. Egan, Springfield, Ill.: Illinois, not being a registration state, does not have a registration of vital statistics, but has a system of mortuary statistics—not as complete as it might be, but still not bad. Illinois does not require the death to be reported except in certain cities where the reports are made to the proper health official. Throughout the state, outside of these cities, reports are made to the State Board of Health, and a fee of 25 cents is paid for every death reported. I believe that in Illinois we get reports of 90 per cent. of the deaths.

Dr. W. H. Sanders, Montgomery: In Alabama, while we have had laws providing for the registration of births and deaths for many years, for reasons that it is not necessary to enter into now, those laws have not been enforced in all parts of the state. At the last meeting of our legislature more rigid laws governing this matter were enacted than heretofore had existed. We are now making a vigorous effort to call out the vital and mortuary statistics for Alabama, and we hope that our efforts will bear fruit. In Alabama and the other southern states we labor under one difficulty which does not confront the states and people of the north, viz., our large negro population. In some counties in Alabama there are five, six, seven and eight times as many negroes as white people. You will understand the difficulties that surround the collection of vital and mortuary statistics where the population consists so largely of negroes. It is impracticable in a section of the country like that to provide a law that will absolutely require a burial certificate. The undertakers are not scattered all through the county. We are trying to overcome the difficulties, however, and believe that we shall be able to do so. Of course, in those parts of the state in which the negroes are so largely in the majority the midwives do all or a great deal of the obstetric work. In getting up our recent form of death certificate we have added one item or heading to our form of certificate which I have never seen in any other form: "Did the deceased undergo a surgical operation, and if so, when and of what nature?" We have often received certificates of death in which peritonitis, septicemia, or shock would be assigned as the cause, when it was obvious that there must have been something back of these causes and when possibly the real condition back of them was an operation which had been performed only two or three days before.

Dr. C. L. Minor, Asheville, N. C.: I am satisfied that under present conditions, in the rural portions of the black belt of the south, the registration of vital statistics is impossible. The south is almost a purely agricultural region, where the farmers live scattered over a large area, often far from the nearest town, doctor or undertaker. Under these conditions, how can we hope for reliable vital statistics? Look at the conditions in Germany, where vital statistics are the most accurate and satisfactory in the world. Small villages are scattered everywhere, at short distances, and there is a paternal system of government which can force every physician and every citizen to obey its orders. While I do not wish to be a pessimist, it seems to me that in the south, despite the most faithful and earnest efforts of our doctors, we can not hope for satisfactory results in this direction until the country is more thickly settled. In North Carolina, where I live, there is satisfactory registration in the towns, but not in the country, and we can not expect an overworked and busy country practitioner, going night and day, and very often far from the court-house, to make full reports of his work—not to speak of those large areas where there are no doctors at all.

Dr. George W. Webster, Chicago: Difficulties in securing and enforcing legislation of this character are not confined to the negro population of the south or to the ignorant people. In Illinois, for example, the state board had introduced and passed, four years ago, a rather satisfactory vital statistics bill. This was in operation about two years, then Mr. Miller, the ex-speaker of the House of Representatives, asked for its repeal on the ground that it was too much trouble for his constituents to obtain legal permission to bury their dead. Illinois would have had no bill at all had it not been for the fact that we accepted the present law as a compromise, thinking that it would be better to hold on to that and use it as a lever in securing some such law as is now recommended by the American Medical Association. Until the House of Delegates and the medical profession rise up and help us in educating the people and the legislature to the fact that vital statistics are absolutely necessary as a foundation for public health work, we must be content with the present law.

Dr. H. M. Bracken, Minneapolis: The question on the birth blank relative to prophylaxis against ophthalmia neonatorum is of great importance. A movement looking to the prevention of this disease was taken up in the Section on Ophthalmology two years ago.

Dr. S. S. Crockett, Nashville, Tenn.: In furnishing results of mortuary and vital statistics, however much we appreciate the importance of it, we shall never accomplish anything either in the south or anywhere else until the people themselves appreciate the importance of it. They have to be taught the desirability, the importance and the value of it. In Tennessee we had an amusing defeat of a vital statistics bill four years ago. We had drafted a great improvement over our present law, and when it came to the question of undertakers' certificates for every burial it was charged that the undertakers were behind the scheme, and that they were the men that were pushing it; that it was really an undertaker's bill. It was shown that in about twenty counties in the state there was not an undertaker; that the people did their own undertaking, and we shall have to develop undertakers in Tennessee before we can accomplish results.

Dr. J. H. White, New Orleans: Would it be possible to obtain from the United States government the franking privilege for the purpose outlined by Dr. Hurty? While it may seem a small matter, it is a huge task to pay postage on all the work of the health office, and the franking privilege would be of inestimable value to the health officers of the United States. It would enable them to gather material from everywhere, and place the returns in the hands of every doctor in the United States, so that he would know what was going on in reference to vital statistics in Illinois, or in any other state of the union. I believe that vital statistics could be collected in the south to some extent by making laws and enforcing them as well as may be, but not tabulating all the statistics. We could take such areas as it is absolutely impossible to get those statistics from, and leave them out of consideration in the tabulation, just as the census bureau does in tabulating the cotton returns, or any other returns of the products of the southern states, saying that such districts have not yet reported. In this way we would get what was available. In certain sections of the south it is impossible to get vital statistics because the inhabitants are miles away from civilization. They have no midwives, and no doctors.

Dr. H. B. Hemenway, Evanston, Ill.: On what basis does Dr. Wilbur select certain towns in non-registration states, for record in the vital statistics? For instance, Evanston has its own local law, efficiently enforced, which compels the registration of death before the body may be removed from the place in which the death occurs, and yet I find that Evanston is not mentioned in the tabulated statement. Physicians are accustomed to issue death certificates without seeing the body. There is no identification of the body, and once in a while it becomes a matter of legal importance to identify a certain body. Life insurance companies always call for a certificate of death, and really, the record is of little value in many cases simply because the physician has not seen and identified the body. The certificate ought to state that the physician was in attendance before death, and that he has seen the body.

Dr. C. L. Minor, Asheville, N. C.: What does the poor mountaineer do when, often far from any physician and more often from an undertaker, his dear wife dies? He makes his own rude coffin, places his dear dead in it, wrapped in a sheet, digs a grave with his own hands, and places her there to wait for the great hereafter. These deaths, reports of which never reach our registrars, are what interfere with the accuracy of vital statistics in the country, and makes them reliable only in cities, towns, villages or thickly settled districts. Look at the records of births. Doubtless as soon as the negro woman, as she is already doing in the cities, approximates to the ways and constitution of the white woman, she will need a doctor's presence, but the average corn-field negro woman has her baby without any assistance whatever. I know of the case of a negro girl who, coming back from church with a party, left them to go into the bushes, had her baby, picked it up and rejoined the crowd before they got home.

Dr. Cressy L. Wilbur, Washington, D. C.: In reply to the question as to the basis on which cities were admitted to the registration area, the comparison was made at the time of the last decennial census in 1900. The returns were collected from the registration authorities of the cities and an independent enumeration of deaths was also made by the census enumerators. The total number of deaths, from both sources, being established as a basis, those cities in which the registration amounted to 90 per cent. of this total were accepted as registration cities, and those falling below that standard were omitted. In a general way, however, the registration of deaths in Illinois, outside of Chicago, in those cities having permits, is not as good as that of the majority of cities in non-registration states, because in many instances when deaths have occurred in cities and when the bodies are taken out of the cities and not buried in the municipal cemeteries, permits are not issued. We do not consider the returns fully reliable. I do not wish to refer to the character of the work done by the State Board of Health in a critical way. I know that Dr. Egan has done very creditable work with a very imperfect tool, and I am sure that when he becomes better equipped he will be surprised to find that he is getting an increased number of returns, and that he can place greater dependence on them as full and reliable. I do not think that they are so now.

Dr. T. D. Tuttle, Billings, Montana: We have a registration law in Montana, and we have Hungarians and Finns and everything else, and occasionally an American. We are getting fair results there, but I believe that any of you can kill a registration law as soon as it is passed by your legislature if you do not handle it with a little judgment. Last winter, when the snow was about fifteen feet deep in our gulches a child died. It would have taken the father twenty days to reach town. If I had filed a complaint against that man for not having a burial permit I believe that the thing would have been made so public that our law would have been killed the next winter. You can not get a death certificate sometimes in twenty days. The farmer whose wife dies, and who has no money to bury her, makes a box, and buries her himself. If he comes in as soon as it is practicable to get to town that is satisfactory. If the death certificate is filed honestly, and as quickly as it can be done, I do not believe you can successfully prosecute that man. I doubt if there is a doctor in Montana who does not promptly file his birth certificates. The majority give the name. Dr. Hurty suggests that the name should be given in one day, but we could not get the name in that time in any event. I think that ten days is better. We have some people who are worse than the negro. Men who can not read, and who do not go to the post-office once in ten days are common with us. Letters do some good in our state, but the foreigners do not read them. Yet we are getting pretty good returns by pounding at them, and not prosecuting them.

Dr. J. N. Hurty, Indianapolis: These letters to mothers are doing good work. We invite them to write to us. That puts a considerable burden on the state board, and I have felt it, as the secretary, but they bring us directly in contact with the people, and they understand it. Numerous mothers' societies and teachers' conventions have taken up the subject, and so, as this education is going on, they are finding out that it is of the utmost importance to them to have these records made. We had applications for almost six hundred transcripts of births and deaths last year, and we made a missionary of every one of those applicants in the cause of correct vital statistics. I think that this has done much good in Indiana, and we do not despair of getting accurate death records from away out in this country, where people bury their own dead. You know the feeling where there is a death in the family. In one of my excursions I found parents burying their child, dead of diphtheria, in a home-constructed coffin. They were poverty-stricken people, but they were ready to listen to us, and they desired greatly that the death of that child should be recorded. They only needed to know about it. I believe that our southern brethren can secure good statistics from the negroes by introducing into their laws the clause in the Indiana law, which provides that in the event of burial without permit the coroner shall disinter the body and hold an inquest and secure the data. What a commotion disinterment makes in a community! It was only last week that we had a disinterment, although our law has been in force many years. The physician said that he was too busy to make out a certificate. He didn't "believe in health laws nohow," for he said so. He said to the undertaker that he would stand between him and the law. It cost that physician $80. He found plenty of time to attend the trial. He was not too busy to attend the inquest, and the educational value to the community was very great. That physician will be very much less busy the next time he has a case of this kind. At first, the people were angry. Many said that it was an outrage, but when they found that a law-breaking physician caused all that trouble they took a different view.

An Error Sometimes Made in Examination of Sputum for Tubercle Bacilli.—W. H. Buhlig, Chicago (*Quar. Bull. Northwestern Univ. Med. Sch.*), points out that in the attempt to hurry a preparation of sputum for microscopic examination, the smear is often heated before it is quite dry, producing in this way artefacts that are sometimes with difficulty differentiated from tubercle bacillus.

A NEW METHOD FOR THE QUANTITATIVE ESTIMATION OF ALBUMIN IN URINE.[*]

EDWARD H. GOODMAN, M.D.
Physician to the Dispensary of the Phipps Institute for the Study, Treatment and Prevention of Tuberculosis; Dispensary Physician to the Presbyterian Hospital; Assistant Instructor in Medicine, University of Pennsylvania.

AND

SUZANNE STERN.
PHILADELPHIA.

In the book on urinary analysis by Neubauer and Vogel sixteen closely printed pages are devoted to the question of the quantitative determination of albumin in urine. Of the many methods described but two are in general use, the gravimetric and the Esbach methods. The former is complicated and tedious but accurate, while the latter method, reported by Esbach in 1874, aims to present a relatively easy and accurate procedure. Many factors must be taken into consideration in using this method: The specific gravity must be between 1006 and 1008; there must be less than four grams of albumin in a liter of urine; the specimen must be acid, and, as pointed out by Schulz and later by Christensen (quoted by Neubauer and Vogel), the temperature plays an important rôle. Neubauer and Vogel,[1] after a careful review of the literature pertaining to the Esbach method, state that even for a moderately satisfactory estimation of the quantity of albumin it is absolutely unreliable, and that an estimation of the albumin by the quantity thrown down on boiling is almost as exact. When, however, all precautions are taken as to temperature, specific gravity, etc., one can determine whether the amount of albumin has increased or decreased.

The Esbach method has for a generation been firmly established in every laboratory, and where tradition and common usage have rendered a custom almost a law, it should be with a great deal of trepidation that one attempts the task of annihilation and substitution. This is, however, the object of our paper, and we believe we are now in a position to speak with authority and definiteness concerning the method advanced by us in a preliminary report published in The Journal, July 4, 1908.

For some time past work has been carried on in the laboratory in an endeavor to devise some simple, rapid and exact method for estimating the quantity of albumin in a given specimen of urine. A brief report of our failures may prevent others from attempting work along similar lines. The first thought which naturally arose was to measure the ring of albumin obtained by Heller's test, after standing a certain length of time, and after many wearying attempts this had to be abandoned as impracticable.

We then tried the various color tests, the Biuret, the Millon, the xanthoprotein and the Adamkiewicz, endeavoring to establish a color scale with which a specimen of urine might be compared as is done with the Tallquist scale for hemoglobin estimations. Of these tests the Adamkiewicz alone promised success, but the gradations of color were so slight that this method was ultimately discarded. The other tests were worthless as quantitative methods.

---

[*] Final Report from the Private Laboratory of Dr. John H. Musser. Read in the Section on Medicine, Medical Society of the State of Pennsylvania, Cambridge Springs, Sept. 14-17, 1908.

[1] Neubauer and Vogel: Analyse des Harns, ed. 3, 1898, p. 865.

About this time there appeared a paper by Tsuchiya[2] offering a *modification* of the Esbach solution in the form of a solution of phosphotungstic acid in 96 per cent. alcohol and hydrochloric acid, which, he states, gives results more nearly approaching those obtained by weighing than does the original Esbach solution. He gives many tables which substantiate this claim and summarizes his conclusions as follows:

1. With normal urine there is no precipitate, as is sometimes the case with the Esbach reagent.
2. The precipitate from albuminous urine settles more regularly than with the Esbach solution. Foaming or floating of the precipitate is never seen.
3. The method is more exact with moderate room temperature than is the Esbach method.
4. Small amounts of urine are precipitated as well as are the larger amounts. This is especially important for febrile urines, as Esbach himself said his method was not suitable in these instances.

It occurred to us that use might be made of this solution of Tsuchiya as a basis for a titration method, and it remained but to determine the amount of albumin which would first cause a cloudiness.

We dissolved 1 gm. of crystallized egg albumin in 100 c.c. of distilled water (Solution A). Of this we took 1 c.c. and diluted with 9 c.c. of distilled water (Solution B) so that in the 10 c.c. there was 0.01 gm. of albumin, in 1 c.c. 0.001 gm., and in 0.1 c.c. 0.0001 gm. We put in a test-tube 5 c.c. of the following solution:

Phosphotungstic acid	1.5 gm.
Hydrochloric acid (conc)	5 c.c.
Alcohol, 95 per cent. q. s. ad	100 c.c.

We found that if the solution of egg albumin (Solution B) were added with a *pipette graduated in 0.1 c.c.* it took 0.1 c.c. to cause a cloudy precipitate with the phosphotungstic acid; in other words, 0.1 c.c. of the albumin solution contained 0.0001 gm. albumin.

To prove the delicacy of this test we took 1 c.c. of Solution B and diluted it with 9 c.c. of distilled water so that in the 10 c.c. there was 0.001 gm. albumin, *in* 1 c.c. 0.0001, and in 0.1 c.c. 0.00001 gm., and we found *that it required exactly 1 c.c. or 0.0001 gm. albumin to* cause a precipitate.

Having established the fact that the acid solution precipitated exactly 0.0001 gm. albumin, we applied our method to urine.

First the Heller test is made, and if much albumin is present the urine is diluted 1 in 10; if not, undiluted urine is used. Five c.c. of the phosphotungstic acid solution are put in a test-tube, and then with a 2 c.c. pipette graduated in tenths of a cubic centimeter, the filtered urine is added to this, shaken after the addition of each tenth and urine added until a whitish cloud appears. The number of tenths of a cubic centimeter is read off and expressed in terms of 100 c.c.

For example, if it takes 1 c.c. of diluted urine (1 in 10) there is 0.0001 gm. albumin in 0.1 c.c. of undiluted urine, or in 100 c.c. there is 0.1 gm. albumin, or 1 gm. in 1000 c.c. On the other hand, if 0.7 c.c. diluted urine (1 in 10) is used, then 0.07 c.c. undiluted urine equals 0.0001 gm. albumin, 7 c.c. diluted urine equals 0.01 gm. albumin, and 700 c.c. equals 1 gm. albumin. The following equation gives the percentages:

700 : 1.0 :: 100 : X or 0.142 per cent. or 1.42 gm. per thousand.

Since publishing the first report of this method we have made but one slight modification, and that is the use of water acidulated with acetic acid instead of ordinary distilled water for diluting. This we found especially useful with alkaline urine, which must always be made acid before examining. It must be remembered that if undiluted urine throws down a precipitate *after the addition of 0.1 c.c. it must be diluted with* nine parts of water and the test repeated, as there may be so much albumin that less than 0.1 c.c. of undiluted urine is required.

*In the columns "Esbach old" and "Esbach new" are the results obtained by using the Esbach albuminometer with the original picric acid solution and the phosphotungstic acid solution of Tsuchiya, respectively. The results by all four methods are expressed in per cent.

Our method has in all instances been controlled by the gravimetric estimation, made according to Englander's recommendation;[3] and in addition we have made determinations with the Esbach albuminometer, using the original picric acid solution and the phosphotungstic acid solution advocated by Tsuchiya. A study of the accompanying table shows three things: first, that the Esbach albuminometer used with the Esbach reagent is absolutely unreliable; second, that the phosphotungstic acid solution of Tsuchiya is an improvement and approaches more nearly the results obtained by weighing; third, that the determination of albumin by means of our titration method is startlingly exact, in but few instances varying from the gravimetric method, and then in only a slight degree.

We have had opportunity to study but one specimen of pleural fluid (No. 16). In this instance the result was not very satisfactory and more work must be done in this direction before a final answer is given as to the usefulness of the method in such cases.

In conclusion, our method for determining the amount of albumin by titration is to be recommended on account of its simplicity, accuracy and the rapidity with which one obtains results. It is applicable to urines containing but faint traces of albumin, such as those in cases of febrile albuminuria, which are not suitable for the Esbach method. The method is also accurate for large quantities of albumin. So far we have been unable to find any sources of error in our method such as must be taken into consideration with the Esbach albuminometer. We propose to study this question still further, making it the basis of a later communication.

NOTE.—Since we wrote this article, a paper has appeared in THE JOURNAL, Oct. 31, 1908, p. 1511, by Dr. H. R. Harrower, describing a "new instrument for the rapid and accurate determination of albumin in the urine." This instrument is for use with the reagent mentioned by us in THE JOURNAL, July 4, 1908, in connection with our new method of albumin determination, and has a bulb for 5 c.c. of the reagent, above which is a 3 c.c. tube graduated in tenths of a c.c. Harrower makes use of our determination of the amount of albumin precipitated by 5 c.c. of the phosphotungstic acid solution, and reads off in his tube the amount of urine which must be added to produce a cloud. We see in Harrower's instrument a complication of our method. We put 5 c.c. of the reagent in a test tube and add the urine from a pipette graduated in tenths of a c.c. reading off the amount of urine producing a cloud. Harrower's method is unnecessary, as essentially his instrument is nothing but a test tube and a graduated pipette in one. Apart from the expense of the instrument, the difficulty in keeping it clean is not insignificant. As our method requires but a test tube, a 5 c.c. pipette for measuring the reagent, and a 2 c.c. pipette graduated in tenths of a c.c., we think Dr. Harrower's instrument is unnecessary, as no time is saved and many disadvantages are connected with it which are absent in our procedure.

Clinical Notes

TREATMENT OF COMPOUND COMMINUTED FRACTURE OF BOTH TIBIA AND FIBULA

J. W. INGRAM, M.D.
MARSHFIELD, ORE.

The case in question was that of a young man, aged 27, who, while employed as a railroad brakeman, was injured Nov. 6, 1906, by a collision of the locomotive, on which he was riding, with a carload of logs.

I saw the patient Dec. 4, 1906, twenty-eight days after the injury was received. During this time the patient had been treated by the company physician, with occasional consultations with the family physician. He had been told that an amputation of the leg would be the only procedure. This was asked for by his physicians on several different occasions, but was refused by both the patient's father and the patient himself.

After a careful examination I found that a compound comminuted fracture of both bones existed at about the junction of the lower with the middle third of the leg. The communication on the external side was from two and one-half to three and one-half inches in length, through which splintered portions of the fibula were removed, in all: I should judge, about one inch. The two fractured ends were lying at an angle, with the apex outward, and so dense had become the adhesions that to replace them seemed impossible, and I deemed it better surgery to trim off the ragged ends and not attempt replacing them. On the internal surface a communication varying from two to three inches in length existed: through this opening one-third of the circumference of the tibia was removed for a distance of four inches, extending into the medullary canal. About midway of this splintered portion the tibia was fractured completely across. A free flow of pus was coming from both wounds.

After removing the splintered portions of bone, which was done on Dec. 8, 1906, at the Mercy Hospital, North Bend, Ore., and making the wounds as nearly sterile as possible, the next problem that presented itself was the nature of the dressing to be used. I had carefully considered the plaster-of-Paris dressing with a glass window, with many other methods and appliances, but found none of them suitable for this particular case. In the first place, it would need multiple daily dressings for some time, daily irrigations, and at the same time the minimum amount of disturbance and as near absolute rest as possible if union was to be hoped for.

I, therefore, devised the following method, illustrated by the accompanying diagram. I took the ordinary perforated metallic posterior splint, put a few layers of cotton, adjusted it to the leg so that it would fit snugly from the knee to the heel inclusive. At the site of the wounds on either side I removed a semicircular piece of the splint in order to allow free access to the wounds. This was made firm by a few bands of one-inch adhesive plaster encircling the leg. This dressing held the bones in perfect apposition just as long as an equal pressure could be maintained on the leg for the entire length. This was accomplished by the use of an extra large pair of suspenders of the pulley type, with as little elasticity as possible (illustration).

I first applied a piece of adhesive plaster, two inches in width, one inch above the wound, allowing it to encircle the leg completely, then passed it through a buckle and around the leg again. Into this buckle were hooked the ends, A A, shown in the diagram. I next passed a similar piece immediately below the wounds, treating it in the same manner, into which was buckled the end marked B in the diagram. Still another piece was passed over the heel, including the heel by cutting a slit in the center of the adhesive plaster; into this piece was buckled the end C, as shown in the diagram. By the use of the suspension used, as shown by the drawing, an equal pressure was maintained on all portions of the leg at all times and at all angles. The two posterior straps, D D, were separated by a steel rod five inches in length, hooked at either end into the straps, with an eyelet in the center into which a rope was tied and in turn run through a pulley fastened into the ceiling and then to the head of the bed.

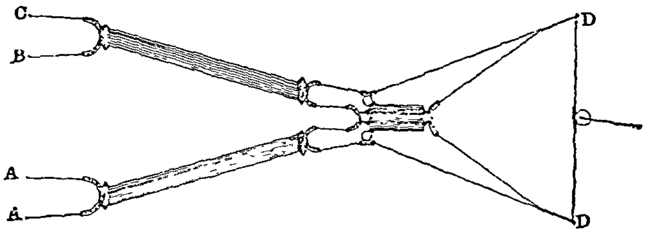

Diagram of suspension apparatus used in compound comminuted fracture of tibia and fibula.

This suspension was used during all irrigations and dressings, allowing the leg to be raised with the least amount of disturbance to the parts possible. The leg was thus raised when the bed-pan was used and when the bed linen was changed. At no time did the patient complain of any uneasiness or pain while the leg was being raised or lowered. This treatment was continued for about sixty days. During the daytime the leg was allowed to rest on a pillow and at night raised just sufficient to be clear of the pillow beneath.

To avoid soiling the dressing in the splint and to keep the water from finding its way beneath the cotton was a problem to be considered, and one which, in fact, had to be solved if I hoped to be able to keep the one splint on for any length of time. The difficulty was overcome in the following manner: After thoroughly adjusting the splint I applied a medium thickness of cotton over the entire surface of the splint, allowing it to come up on the leg about half an inch for the entire length of the splint; then over this I applied a free coating of collodion, thus sealing it up most thoroughly. After about sixty days this dressing was removed. A perfect union had taken place; the leg was found to be in a perfectly healthy condition, with no signs of heating or absorption of moisture from the constant irrigations. The patient was dismissed from the hospital, with both wounds healed, with the exception of a slight opening, which healed in a few days without difficulty. This was just seventy days after I first saw him.

The question has since presented itself to my mind whether a more permanent suspension, that is, one without any elasticity to it, would be of better service than the one which I used in this case. In case the patient should jump in his sleep there was no suddenness to the stoppage of the leg should he raise it and again drop it, as there would be in an ordinary leather suspension.

It is easy to see by the accompanying drawing that when the patient would raise the upper portion of his leg the various straps would loosen and adjust themselves in such a manner as to keep up a constant and even pressure on all parts of the leg at all times. To this method of treatment and mobilization of the parts I credit the good results in giving the patient a comparatively good leg with the least noticeable limp.

RADICAL TREATMENT OF HEMORRHOIDS BY EXCISION.

JOHN A. HAWKINS, M.D.
Professor of Diseases of the Rectum in the University of Pittsburg; Rectal Surgeon to St. Francis Hospital.
PITTSBURG, PA.

In *American Medicine,* June, 1901, I described an operation for the radical cure of internal and external hemorrhoids by excision, and a clamp used in this operation. The results of more than 500 operations by the excision method in private and hospital cases, after more than 500 operations by the clamp and cautery, have satisfied me that the first-named method is the only surgical treatment for hemorrhoids. Excision by the method I advocate in no way resembles Whitehead's operation, which I fervently condemn.

Since the publication of the article above referred to I have modified the operation somewhat, and at the present time in many cases use no special clamp, but pick up each tumor with ordinary hemostats and excise and suture the pedicle.

In the article just mentioned I described a method by which I clamped up the tumor in its entirety close to its base, shaved off the tumor close to the thin-bladed narrow clamp and then passed and tied a deep suture above the end of the clamp and passed the continuous suture under the clamp through the pedicle from one side to the other, then over the clamp to a point about one-fourth inch below the entrance of the preceding puncture, and so on until the entire pedicle was sutured. I always left the suture loops very loose so as to allow the clamp, when loosened, to be withdrawn, after which the suture was drawn tight, loop after loop, until the cut edges of the pedicle were approximated, when the end of the suture was tied below the lower end of the pedicle.

With the operation as above briefly described the results were good, as the tumor was pulled into the jaws of the clamp just desired, especially where the parts are uneven and much distorted.

Of late in using the clamp I have been using a No. 2 chromatized catgut interrupted suture for the mucous membrane (internal hemorrhoids) and a fine black silk for the skin (external hemorrhoids) suture with even better results than with the continuous catgut suture.

The operation in detail is as follows: The patient is prepared in the usual manner, the bowels are emptied by a cathartic and an enema given three hours before time of operation. The anal region is shaved and cleaned thoroughly. After complete general anesthesia the sphincters are divulsed with the fingers and the tumors are located and picked up with hemostats. The lowermost tumors are removed first to avoid any blood from above obscuring the view during the operation. The hemorrhoid is drawn into the clamp with thumb and forceps in its entire length, including the internal and external portions, if both are present; then the mass is shaved off close to the tightly closed clamp and the sutures are introduced. I am in the habit of passing a suture or ligature deeply through the tissues immediately above the end of the clamp, this ligature passing under the artery leading into the tumor, and I leave the ends of this ligature long so as to use it for a tractor if for any reason the clamp should slip or it be necessary to draw out the pedicle. The sutures are now passed beneath the clamp at intervals of three-sixteenths or one-fourth of an inch and the ends left long enough to tie. After all are inserted the clamp is removed and the sutures are tied, the pedicle being steadied by the traction suture and the canal being held open by my narrow steel retractors. The sutures having been tied and cut short, the next tumor is taken up and treated in the same manner, after which the pedicles are again examined, the traction sutures cut short, and a narrow strip of gauze inserted into the anal canal, its end protruding. This strip of gauze is left in for only twenty-four hours, then it is soaked with hydrogen dioxid, which softens its adhesions with the cut surfaces, after which the bowels may be moved by a dose of licorice powder or castor oil. When the patient expresses a desire for an evacuation of the bowels the nurse injects two to four ounces of sweet oil into the bowel and after the evacuation only the outer parts are washed. I have never seen infection follow this operation. A gauze compress is applied, over this a compress of sterile oakum, and all held in place by a triangle bandage.

The bowels are moved in twenty-four to forty-eight hours. Opiates are rarely given and the patient gets out of bed to urinate. The patient is kept on liquid diet until the bowels move, then light diet is allowed. In four to six days (or earlier if he feels able) the patient is allowed out of bed with full diet, the bowels if constipated being moved every other day as described above.

It is extremely rare to find the wound not completely healed within ten days.

An ointment of extract of hamamelis 8 gm. (6 scruples), phenol 1.25 gm. (19 grains), and calomel 1.25 gm., in zinc oxid ointment 20 gm. (5 drams), twice daily through a pile pipe, and also after the bowels move, hastens the cure, with comfort for the patient.

Note:—The original operation with clamp and continuous suture has been described by others on several occasions within the past seven years, but the date of the original article, June, 1901, precludes the claim of priority by others.

ISCHEMIC CONTRACTURE WITH SECONDARY ULNAR NEURITIS, THE RESULT OF BRACHIAL THROMBOSIS.

G. M. ASTLEY, M.D.
PHILADELPHIA.

In view of the fact that numerous papers have recently been written on the subject of ischemic muscular contractures, I thought it of interest to report the following case, because in its course the sequence of the various steps that occur in typical cases of Volkmann's paralysis is presented, without the complicating factor of pressure from bandages, which has been thought by some to be a factor in producing the deformity from contracture, after some cases of fracture near the elbow joint.

For the privilege of reporting this case I am indebted to Dr. Thomas R. Neilson of the Episcopal Hospital of Philadelphia; and, for the notes made at the Orthopedic Hospital, to Dr. Francis W. Sinkler.

The notes here presented are those made at the time in the hospital.

Patient.—A salesman by occupation, aged 42, was brought to the hospital at 7:30 a. m., June 10, 1905, on account of loss of use of the right arm and severe pain. His family history was negative.

Personal History.—The patient denied having had any venereal affection of any kind. He had not been a user of tobacco or stimulants to excess. There was no history of infectious disease save frequent attacks of grip. Seven years ago he began having nasal trouble, which persisted and became much worse. Severe head pain and insomnia later developed. The patient almost completely lost his sight and sense of smell and became a mouth-breather. He became very despondent and had intervals of condition bordering on mania. His condition about eight months ago was diagnosed as sphenoidal sinusitis. Treatment was rapidly followed by improvement. About a year or a year and a half before admission to the hospital the patient was told that he had mitral regurgitation with cardiac hypertrophy.

Present Condition.—On the day of admission the patient said that he arose feeling perfectly well; that he did some slight work about the house and wrote three letters before the present trouble appeared. (He was right-handed.) About 6:30 a. m. he began having severe tingling in the finger-ends of the right hand. The sensation rapidly became one of great pain, and extended upward, involving the hand, wrist, and ultimately the whole forearm. He became alarmed at the condition and came to the hospital, arriving about an hour after the onset of the trouble. On his arrival the right hand and forearm were pale and cold; absolutely no swelling was present, and sensation was entirely absent. No pain was complained of when any part of the forearm was pricked quite sharply with a pin. No radial pulse was palpable; no pulse at elbow, none in arm. High up in the axilla a faint pulsation could be felt. The patient could not move his fingers. On account of the severity of the pain morphin was given. Three-quarters of a grain, given during a space of about five hours, had little effect. The arm was wrapped in raw cotton, hot-water bags kept about it and was elevated. Nitroglycerin and veratrum were given internally.

6 p. m.: A very faint radial pulse could be felt, and the area of anesthesia had lessened now including only the ulnar side of the hand and four fingers.

10 p. m.: The patient's condition was about the same; he still complained of severe pain. The fingers and hand had become quite rigid. There was slight flexion at the wrist.

June 11: The patient was delirious on the preceding night and out of bed several times. He did not know where he was. This forenoon he saw a patient in a neighboring bed, suddenly realized where he was and apparently remained rational after then. His hand and forearm were somewhat swollen. The radial pulse was not palpable; the hand was warm; the veins filled slowly from below when emptied. The fingers and hand were rigid; the wrist and fingers somewhat flexed and the sensation in the fingers was not very acute.

June 12: The temperature was up to 102. The previous night the patient was again delirious, not as badly as on the preceding night. Below the elbow the forearm was much swollen. The skin was red, tense and shining. The local temperature was much above the surrounding. The forearm was quite tender to the touch. The first metacarpal interspace was swollen and tender. The local condition was not as severe as above. In both instances inflammation appeared to be in the deeper tissues. There was not a superficial cellulitis There was no apparent wound for infection. In the afternoon the patient's condition was not improved. Five incisions were made in the forearm over the swollen area and a quantity of serum liberated. The patient was again delirious in the evening.

June 13: The swelling was considerably reduced and the tenderness less marked. The hand was about the same. The radial pulse was re-established.

June 15: The swelling was reduced and temperature down. Sensation returned everywhere. The fingers were still quite rigid. There was no more pain.

June 20: The wounds were healing. Rigidity was present.

June 30: The wounds were almost entirely healed. The patient had been having massage for about a week. The tendency to contraction was quite marked.

July 4: The patient was referred to the dispensary. The patient was seen at irregular intervals during the next two months. An atrophy and claw hand developing, he was referred to the Orthopedic Hospital. The following notes were kindly furnished by Dr. Sinkler:

NOTES FROM ORTHOPEDIC HOSPITAL.

September 8: The skin over the dorsum of the hand was glossy. The thenar and hypothenar muscles and the Interossei were wasted. The fourth and fifth fingers could not be extended within 40 degrees of straight, but could be fully flexed. The fingers could not be separated or abducted. There was anesthesia of the outer aspect of the fourth finger and all of the fifth. Some lessening of sensation of the other fingers from tip to distal phalangeal articulation, and anesthesia of the ulnar side of the hand. Massage and electricity were prescribed to be administered three times a week.

September 15. The patient felt pain in the fifth finger when stuck, but felt no sensation to touch; that is, he had no analgesia, but anesthesia.

September 22: The patient moved his fingers a little better.

October 13: The dynamometer showed right hand 10; left, 65. The patient was better; wrote better. Sensation was still impaired in the fourth and fifth fingers at the hand.

Diagnosis.—Ulnar neuritis. In a note Dr. Sinkler says that possibly division had occurred through incision over the course of the nerve.

These notes were made about two months after the last of my own.

The case then shows a complete ischemia caused by a thrombosis or an embolism, probably the former, I believe. The first evidence of contracture was rigidity, which was sufficient to attract attention at 10 p. m., approximately fifteen and one-half hours after the beginning of the trouble, though it may have been present earlier. This appeared in spite of the fact that there had been some circulation for four hours, at least a slight radial pulse having been detected at 6 p. m. At this time there was also a slight restoration of sensation.

On June 15, 1905, five days after the injury and three days after the incisions were made, the notes say that sensation had everywhere returned. This, I think, shows positively that the conclusions by the physicians at the Orthopedic Hospital, that the nerve had been severed at the time the incisions were made, to be erroneous. Nor do I believe that there could have been any involvement of the nerve in the cicatrix, for the incision was in the upper third of the arm and did not involve muscular tissue.

At the time of the patient's discharge "the tendency to contracture was quite marked." The hand was flexed at the wrist, the fingers semi-flexed, and not in the typical *main-a-griffe* shape.

I saw the patient but seldom during the interval between discharge and admission to the Orthopedic Hospital and do not know when the ulnar neuritis developed.

The points of interest in this case are, then:

1. A brachial thrombosis or embolism which was not followed by gangrene.
2. An ischemic contracture, as evidenced by rigidity of the hand and flexion at the wrist appearing not later than fifteen and one-half hours after the blocking of the circulation.
3. The re-establishment of the circulation and sensation (nerve conductivity); the sensations are recorded as everywhere present five days after the injury and three days after the incisions.
4. The onset of an ulnar neuritis at a subsequent period, due presumably to a pressure neuritis from the contracture of the degenerated muscle.
5. The probability of some involvement of the median nerve, as shown by the note from the Orthopedic Hospital, "some lessening of sensation of other fingers from the tip to the distal phalanges."
6. The partial recovery at any rate from the ischemic contracture, for when the patient presented himself at the Orthopedic Hospital he could extend the index and middle fingers as well as flex them.

I regret that it has been impossible to find the patient in order to report on his present condition.

Polydipsia in School Children.—G. Paul Boncour, in *Progrès Médical*, Aug. 22, 1908, calls attention to a little noticed factor which he thinks accounts for certain difficulties in school children attributed to other factors. Certain children show a marked inaptitude for work and feebleness of attention, learn their lessons poorly, but seem more apathetic than unruly. According to the parents, such children suffer from headaches, sleep poorly, have irregular appetites, but are inclined to drink large quantities of water. These symptoms appear after the first heat of summer and can not be traced to any organic disease like diabetes, etc. Boncour attributes the nervous symptoms to a bad habit, originating in the desire for water during the first hot weather. The stomach is overloaded and dilated and fermentation and autointoxication result, which in children with a nervous predisposition reveals itself in the symptoms complained of. The desire for water is compared, by him, to a tic. The desire for drink is felt and expressed without reflection. It is simply a bad habit based on an original nervous and psychic debility already existing. The facts demonstrate, he thinks, the necessity of a medico-pedagogic study of school children presenting abnormal symptoms that are liable to be taken as the result of overstraining.

INFLAMMATION OF MECKEL'S DIVERTICULUM SIMULATING APPENDICITIS.

D. A. EWING, M.D.
SEATTLE.

The presence of Meckel's diverticulum and acute inflammation of that rare appendage is of sufficient interest to merit reporting.

This case is especially interesting because it occurred in a man who had previously had two attacks of appendicitis and whose present illness was thought to be due to an inflamed appendix.

Patient.—A rather heavily built man, aged 37. As a boy he had frequent attacks of pain in lower abdomen; had an acute attack of appendicitis five years ago and another one two years ago. For several weeks prior to the present attack he had had an uncomfortable feeling in lower part of abdomen but no acute attacks of pain.

Present Illness.—The patient was taken suddenly with severe pain in the lower part of the abdomen about noon, Sept. 27, 1908. An ice-bag was at once applied, affording only moderate relief. I saw the patient at 4 p. m., when he was in very severe pain and was vomiting bile-stained fluid. The pain was low down on the left side and there was tenderness on deep pressure over both sides of lower abdomen and considerable muscular rigidity, the same on both sides. On account of the thickness of abdominal walls no particular point of tenderness could be found. A soapsuds enema was given and bowels moved, with considerable relief of the pain. Temperature was 98.5; leucocytes were 9,200. At 10 p. m. pain was less; temperature 100.6; pulse 92. Next morning pain was about the same; temperature 99.6; leucocytes 12,000; tenderness and rigidity continued over both sides lower abdomen.

Operation.—Made at 2 p. m. Incision over appendix. The appendix was firmly bound down by adhesions, and when I endeavored to get it to the surface a portion of the lower ileum came into view, showing a diverticulum about the size of a small walnut. Its attachment, as is usually the case, was opposite the mesentery. Its lumen communicated with the bowel by an opening about the size of a dime. It was acutely inflamed and contained no concretions. Its walls were thin, and while we were examining it the diverticulum inflated to twice its natural size. It was easily ingavinated into the bowel and a double row of linen sutures placed. The appendix showed only a mild degree of inflammation and was bound by adhesions. It was removed. The appearance of the appendix showed that it had been the seat of previous inflammation, but the present condition seemed hardly to account for the symptoms that the patient had. The cause of the trouble was probably the distention of the diverticulum and a consequent localized peritonitis; the walls being thin, the diverticulum could easily have been inflated to the size of a baseball.

Postoperative History.—The patient made a good recovery.

Therapeutics

INFANTILE PARALYSIS.

Acute anterior poliomyelitis, though by no means a frequent disease, occurs more frequently unrecognized than any other serious disease of young childhood. The difficulty of its recognition is that a mild attack may leave such slight symptoms that at first the localized muscle debility is not discovered. The future welfare of the muscles affected depends so much on the early recognition of the presence of the disease and its proper treatment that too great care can not be exercised in testing the condition of the four extremities of a child who has had a sudden unexplained febrile attack. Epidemics of this disease occur, but it appears sporadically probably in all parts of the United States. The age of its occurrence is most frequently from 1 to 3 years and it is rare after 5 years of age. It is doubtless a germ disease, which seems to develop most frequently in the summer months, and strikes without premonition as rapidly as does fulminating *cerebrospinal* meningitis.

While most children attacked by the disease have high temperature, vomiting, headaches, and muscle aches, and are acutely ill, others may not be known to have been attacked until it is found that one or more extremities are paralyzed. Convulsions may occur, and the fever symptoms may last from twenty-four to seventy-two hours. There is then rapid improvement in all the muscles except those that are permanently involved. The legs are more likely to be involved than the arms, and a leg more frequently than an arm. If this paralyzed leg is not properly treated the muscles will atrophy, muscle and nerve degeneration will take place, and contractures of the muscles will occur.

Dr. David T. Bowden, Paterson, N. J. (*Journal of the Medical Society of New Jersey*, November, 1908), describes a series of cases of this disease which he saw during the epidemic of 1907, and from his experience advises the following line of treatment:

If the child is seen during the acute or fever stage he would give a calomel purge, encourage sweating by hot packs, hot drinks and hot blankets, and if the fever were high would *administer an antipyretic. He speaks* of using leeches, but does not say where he would apply them. After the fever stage he would keep the little patient as quiet as possible, would wrap up the extremities that have lost their proper circulation in flannel and cotton, and as soon as the tenderness of the muscles had subsided would use gentle massage and muscle kneading, together with electricity. As soon as any contractures in muscles or tendons were noted he would use passive counteracting movements and such apparatus as would prevent deformities.

The form of electricity to use depends, of course, on the ability of the muscles to react. If they react to the faradic current that would be the one to use. If they were so debilitated as not to react to the faradic current, then the continuous current with regular interruptions should be used. Electricity and massage should be kept up continuously for a long period until there seems no further improvement in the muscles. Even in neglected cases it is astonishing how much can sometimes be done by proper massage, passive motion and electricity. If any deformity is starting or is present, an orthopedic surgeon should be consulted and the best possible apparatus applied, while the electricity and massage are kept up.

Bowden urges that no operation should be done in the way of tendon cutting until it has been thoroughly demonstrated that apparatus and physical measures are not successful in diminishing the deformity.

GOUT.

Dr. Oliver T. Osborne, New Haven, Conn. (*Monthly Cyclopedia and Medical Bulletin*, August, 1908), discusses the etiology and treatment of this disease. He says that gout seems to be a disturbance of the metabolism, and "may be defined as a non-infectious, aseptic disease due to a disturbance of the transformation of the protein food molecule, more especially the purin molecule, to the excretion end-product." Hence there is no one cause of gout. This definition "does not diminish the importance of predisposing causes of gout, such as heredity, age, habits, alcohol, *overeating of rich* foods, prolonged mental depression or worry, and such infections as leave lesions of the organs engaged in nitrogenous metabolism." Acute attacks of gout may be precipitated by eating more or less proteins containing purin bases (nucleoproteids). This does not mean that uric acid is a cause of gout, but that foods rich in nucleins, and such combinations of food and alcohol as will produce large quantities of uric acid, will certainly make a gouty condition worse.

It is not necessary for the diagnosis of gout or for a patient to be "gouty" "that he should have gouty joints, chalky nodes, gouty kidneys, concretions, or even shooting joint pains. An increased arterial *tension, increased* force of the heart beat, a little extra amount of urine, a slightly increased frequency of micturition, repeated *gastrointestinal upsets*, skin irritations, nerve pains, frequent headaches, especially occipital," all simple disturbances in themselves, when taken together mean that a gouty condition is present. Any condition that much disturbs the normal metabolism of the nitrogenous food from ingestion to excretion may cause gout, and if this disturbance is continually in evidence or intermittently repeated, confirmed gout may be the result.

"To treat gout properly we should:

"1. Carefully study the functioning of each organ.

"2. Know the kinds and amounts of foods ingested and how well they are excreted, and especially in what form the nitrogen appears in the urine; how much urea, how much uric acid.

"3. Arrange the food and liquids ingested to meet the defects discovered in the functioning of the organs of metabolism and excretion.

"4. Treat or modify all complications present.

"In other words, there is no one way to treat or manage chronic gout." Each *patient must be individualized* as to the food and drink he should take.

"That deposits of urates around the joints at times disappear may be an observed fact, but there is no known treatment, medicinal, electric, hydrotherapeutic or other that will cause the dissolution of such deposits." All good hygiene, such as mental and physical rest, clean, dry air when the patient can obtain it, and such hydrotherapeutic measures as tend to keep the skin healthy will aid in preventing gouty symptoms.

If there is an exacerbation of gout or an acute attack there is no treatment "more efficient than a calomel purge, saline laxatives, *and salicylic acid or some form* of colchicum." An acutely inflamed gouty joint needs "rest, moist sedative fomentations, morphin sufficient to stop the pain, a dose or two *of a coal-tar product*," *if* deemed advisable, and colchicum or salicylic acid, whichever is found to act better in the individual patient.

Osborne has found that 0.10 to 0.20 gram (2 to 3 grains) of thyroid gland substance, given once a day, for a long period, will *many times prevent the* recurrence of acute gouty attacks.

Psoriasis in Children.—*In children*, psoriasis presents itself in localized patchy lesions with silvery white scales, although in cases in which there is much associated seborrhea the lesions are covered by yellowish and fatty crusts instead of by the dry scales of the ordinary type. On scraping with the nail or an instrument the scales *fall in a shower-like* manner. —W. B. Brown, in the *American Journal of Obstetrics.*

THE ANTI-INFECTIOUS POWER OF LEUCOCYTIC EXTRACTS.

Of the great importance of the leucocytes in infections there is no question. They constitute an essential element in those reactions to infection in which phagocytosis takes place. The evidence of actual intraphagocytic destruction of many bacteria is convincing. This is especially true with respect to those bacteria which do not undergo lysis in the serum, namely, pneumococci, streptococci, paratyphoid bacilli and others. Several investigators have been able to extract bactericidal substances from leucocytes, so-called endolysins, which appear to act directly on the bacteria without the adjuvant or activating influence of complement. There is difference of opinion as to the ability of the leucocytes to produce free antibodies as the term antibody is understood ordinarily, and it can not be stated that it has been shown definitely that they produce complement, although Metchnikoff and his followers seem to harbor no doubt but that they can. From time to time it has been suggested that the leucocytes may contain or produce substances that neutralize toxic microbic products, but that such is the case has not been demonstrated clearly.

The most recent work on the anti-infectious powers of leucocytes is that of Hiss and Zinsser,[1] who in a series of papers give the results obtained by them from experiments on the curative effects of watery extracts of leucocytes in infections. Their immediate object was to determine whether or not extracts of leucocytes have any curative effect on established infections. In most of the experiments rabbits were used and rabbit leucocytes. The leucocytes were obtained by intrapleural inoculations of aleuronat which give rise to an abundant and richly cellular exudate. The exudate was withdrawn at the end of twenty-four hours, centrifugated, the serum removed and sterile distilled water added to the cells in amounts about equal to the fluid poured off. The cells were then thoroughly distributed throughout this water and the mixture was allowed to stand for a few hours at 37.5 C. and then was kept in the ice-box until used. Before injecting this fluid the mixtures were thoroughly shaken so that the cell residues were also used. The extracts were then tried by injection into animals, mostly rabbits suffering from the effects of intravenous injections of staphylococci, streptococci, pneumococci, typhoid bacilli and meningococci. In all these infections the extracts of leucocytes seem to have had considerable beneficial action so that many animals survived inoculations even when treatment had been delayed as long as twenty-four hours after infection. In many cases the injection of the extract was followed by a marked fall in the temperature and a rapid return to normal.

Extract of rabbit leucocytes was also used in cases of epidemic meningitis and lobar pneumonia. Twenty-two patients with meningitis were treated, and of these fourteen recovered (63.6 per cent.) and eight died (36.4 per cent.). The study of the course of the disease in individual cases gave the impression that the extract often produced immediate changes for the better in the condition of the patient, especially in the symptoms of nervous origin such as delirium, stupor, hyperasthenia. The quantity of extract administered ranged from 5 to 20 c.c. On account of the promptness of the effect Hiss and Zinsser are inclined to attribute the action to one of neutralization of poisons. In many cases there was marked reduction in the temperature, and in some cases the spinal fluid often became much less turbid after the first injection; this, however, may have been the result of the repeated withdrawal of fluid by lumbar puncture.

Seven patients with lobar pneumonia were treated, a number naturally too small to be considered statistically. The uniformity with which the temperature would fall after a single injection of the extract was noticeable, and, taking it all in all, Hiss and Zinsser gained the impression that the extracts are not unlikely to prove of therapeutic value.

It is clearly evident, as the investigators themselves point out, that the validity of the observations and the soundness of the inferences drawn from the experiments in the human infections can be determined only by much further investigation. It may be said, however, that in infections in rabbits the leucocytic extracts certainly seem to have had a more or less well-marked curative effect. It is, therefore, possible that if it were feasible to use extracts of homologous leucocytes in human infections the results might be better. Naturally the question arises as to the nature of the substances in the extracts to which these owe whatever anti-infectious powers they may possess. Special experiments are reported the results of which indicate that the extracts do not promote phagocytosis. Whether or not they are bactericidal in the test-tube does not appear to have been determined. Some years ago we heard a good deal about the value of nuclein or nucleinic acid in infections, and more recently such preparations have been used to produce a protective preoperative peritoneal leucocytosis and also to produce leucocytosis for experimental purposes. Whether extracts of leucocytes prepared as Hiss and Zinsser prepared theirs contain nucleinic derivatives in so large quantities that the work here reported simply represents a new departure in nuclein therapy remains to be seen. At all events, further work on the anti-infectious properties of leucocytic derivatives is indicated, and Hiss and Zinsser may be congratulated on having reopened an inviting field for experimental study.

THE FOOD VALUE OF NUTS.

In 1906 Prof. M. E. Jaffa, of the University of California, who for a number of years has made a study of the food value of nuts and nut products, published an article[1] dealing with this subject. He has recently revised and extended this article, which is now published as Farmers' Bulletin 332 and constitutes an interesting and useful summary of available data on the flavor, composition and digestibility of the substances in question. As a result of his investigation he finds that nuts represent a concentrated form of food, to even a greater degree than cheese, and when rationally indulged in they are well assimilated and may enter into the formation of a well-balanced diet. They contain valuable amounts of protein and fat, both of which are characteristic constituents of the more common varieties of nuts, of which the walnut and cocoanut may be considered as types. Carbohydrates are the preponderant constituents of nuts like the chestnut.

In most instances it is economically wiser to use nuts as part of the regular diet rather than as a condiment or a supplement to an otherwise hearty meal. Nuts should not be depended on as the main food supply by vegetarians and others who use them in place of meat, but they should be supplemented with more bulky foods with a low content of protein and fat.

Nuts are to be classed among the staple foods and not simply as food accessories, and at usual prices they are economic sources of protein and energy. Peanuts supply these factors cheaply, even as compared with such staple foods as bread and beans. From the various nut foods on the market little is to be gained from the standpoint of food value or economy in their use in place of the ordinary nuts and home-made nut products, especially by healthy persons willing to masticate their food thoroughly and to use nuts in reasonable combinations. Unless some addition has been made, the nutritive value of such special preparations can not be greater than that of the nuts that form their basis. Furthermore, nut butter and similar foods provide a means for pleasant variation in the diet, and they are relished by many who would not care for the unprepared nuts. Though less subject to contamination than many other foods, nuts should be handled and stored under appropriate conditions, and they should especially be protected from dampness and the invasion of insects.

ARMY IMMUNIZATION AGAINST TYPHOID.

A board of medical officers, recently appointed for the purpose, has met in Washington, D. C., this week to investigate the question of the advisability of immunizing the regular army, and in case of war the volunteer army, against typhoid fever.[1] The board is headed by the Surgeon-General of the Army and includes, besides Captain Russell, the bacteriologist of the Army Medical School, such eminent civilian physicians and members of the Medical Reserve Corps as Victor C. Vaughan, Ann Arbor, Mich.; William T. Councilman, Boston; John H. Musser, Philadelphia; Alexander Lambert and Simon Flexner, New York; and William S. Thayer, Baltimore.

The appointment of this board marks an era in the history of the Medical Department of the Army, showing as it does the intention of its authorities to make use of the best medical talent of the country to assist them in solving the important problems which confront military sanitarians, both in peace and war. It was for this purpose that the inactive list of the Medical Reserve Corps, embracing the names of some of the most eminent medical men in the country, was recently constituted, this being the first time they have been ordered to active duty in the service of the United States. The subject which the board considered is of far-reaching importance; the experience of all modern wars has shown that typhoid fever is perhaps the greatest danger which threatens the efficiency of troops in time of war. Great progress has been made by the Army Medical Department in the handling of this disease in time of peace, but it is believed that the conditions in war time are such that more radical measures must be adopted to protect the troops.

The Surgeon-General of the Army has had the question of vaccination against typhoid under consideration for some time, and last spring Captain Russell, the pathologist and bacteriologist of the Army Medical School, was sent to Europe to study the matter, especially in Great Britain and Germany, which countries have had the largest experience with this method of procuring immunity. Captain Russell has recently returned and made a favorable report, and the appointment of this board is the outcome of his recommendation. The general medical public will be interested in the results of the deliberations.

THE PASSING OF THE PRECEPTOR.

With the advance of medical education, with the constantly increasing requirements for admission to the medical school, and with the lengthening and elaboration of the course of study necessitated by the enlargement of the field of medical knowledge, there has almost disappeared from view an erstwhile important factor in medical education—the preceptor. Formerly, before going to college, the student spent a year or more studying with his preceptor, going about with him, seeing his patients, and learning not only how to diagnose and treat disease, but, above all, how to conduct himself in his relation to his patients. His vacations were spent in the same manner, and thus from the beginning he was taught to meet his patients on a plane of personal relationship rather than to regard them merely as scientific problems. The graduate of to-day is often wofully lacking in the personal side of the physician's art, and it may take years of sad experience to teach him what his father unconsciously absorbed while learning the sutures of the skull. Interneship in a hospital can only partially replace this lost opportunity, for, while the young physician observes there the attitude of his chiefs toward the patients, the circumstances are quite different from those of general practice, as he must learn when he first "hangs out his shingle" and undertakes to meet the patient in his own home.

---

[1] Yearbook of the U. S. Department of Agriculture.

[1] See department of General News and Comments in this issue for a statement of the action of the board.

The opportunity which came to the student of seeing patients with his preceptor before entering the medical school and observing the problems which must be met and solved gave him a sense of proportion which comes with difficulty to the student who is thrown without preparation into the perplexities of college life. The former was better able to grasp the importance of the subjects presented to him at college and their relation to the work which lay before him. It has been said that "a lofty scorn for detail is the natural attitude of the immature," and while the present tendency to insist on a preliminary training in the exact sciences is a healthy antidote for this attitude, the actual demonstration by the preceptor of the pre-eminent value of exact knowledge in treating the sick showed the student as nothing else could that generalizations can be based with safety only on a foundation of fact—that knowledge must come before wisdom. The encouragement and example of the wise preceptor taught the lesson that the medical school should be but the beginning of a lifetime of study — study of books, of men, and of things. The comprehension of the meaning of the medical school, the broader view of the opportunities which lay before him gained by the student who studied with the preceptor, particularly if he were fortunate in the choice of his preceptor, led inevitably to a greater interest in the work and to a more intelligent grasp of the subject.

The proper relation of the physician to his professional brethren, the time-honored principles of professional etiquette, and the physician's duty to the community at large were inculcated in the mind of the beginner in a manner which unfortunately has no parallel in modern medical education. Osler says of the "true student" that he may be recognized by three signs —"an absorbing desire to know the truth, an unswerving steadfastness in its pursuit, and an open, honest heart, free from suspicion, guile and jealousy." The passing of the preceptor has removed a powerful influence in the encouragement of such an ideal.

CAUSE OF EROTIC ABERRATIONS IN THE AGED.

The suggestion of Dr. James F. Percy,[1] that the erotic aberrations sometimes observed with approaching senility in men who have previously lived irreproachable lives may be due to some abnormality in the involution of the sexual organs, is worthy of some consideration. Certainly the idea of inducing a moral reform in these patients by surgical means is as rational as the propositions that have been made and extensively advertised in the lay press of reforming juvenile criminals by operations on the brain or even by the simple removal of adenoids. We know very little about the brain centers controlling immoral impulses or how they can be affected by the relief of respiratory obstructions, but we do know that the influence of the normal sexual organs on the psychic functions generally is a real one, and it is not a long step farther to suppose that their abnormalities and disorders may also have effects which sometimes may be relieved by their correction. The cases reported by Percy can hardly be classed as senile dementia except in a very limited sense; there could not have existed any such general organic degeneration and mental decay as we usually understand by the term, but it is not impossible or even improbable that there was a certain impairment of the higher inhibitions without necessarily any general impairment of intellection. In such a case the removal of a peripheral source of irritation, especially a source having so powerful an influence on the emotional life of the individual, might be followed by the best results. Percy seems to have appreciated the difference between these cases and senile dementia when he suggests the possibility of sexual neurasthenics and sexual perverts having "as an explanation of their mental aberration a pelvic rather than a brain pathology."

Medical News

CONNECTICUT.

Personal.—Dr. Stanley R. Benedict, assistant in physiological chemistry at Yale University, has been appointed instructor at Syracuse University.——Dr. Irving L. F. Nettleton, Bridgeport, who has been seriously ill with diphtheria, is convalescent.——Dr. William W. Brackett, health officer of New Britain, has resigned.

Work at State Laboratory.—At the quarterly meeting of the State Board of Health, Prof. H. W. Conn, director of the state bacteriological laboratory, reported on the work being done in that institution. With the appropriation of $7,500 he has established and equipped the laboratory, has examined 1,087 specimens for tuberculosis, 880 for diphtheria, and 528 for typhoid, and has made 974 tests of milk, in addition to other examinations.

Medical Staff Appointed.—The following medical staff has been appointed for the New Britain General Hospital: Attending physicians and surgeons—Drs. John E. Martin, Edward L. Whittemore, Kobert M. Clark, William W. Brackett, Elmer

---

[1] Illinois Med. Jour., November, 1908.

L. Styles, Carl J. Hart, Harry A. Elcock, Ernst T. Froman, and Henry T. Bray, New Britain; William W. Christian, Berlin; E. Parker Sanborn, Bristol; Arthur R. Couch and G. Perry Eldredge, Hartford; eye and ear, Dr. Joseph H. Potts, New Britain; and pathologist and bacteriologist, Dr. Catherine H. Travis, New Britain. Consulting staff—Drs. Arthur S. Brackett and Charles R. Upson, Bristol; Dr. Charles M. Kent, Forestville; Drs. J. Norris Bull and Charles W. Moody, Plainville; Drs. George P. Cooley and Kenneth E. Kellogg, New Britain; Dr. Robert E. Ensign, Berlin; Roger M. Griswold, Kensington; Drs. Oliver C. Smith and Edward B. Hooker, Hartford; and Drs. Harry L. Fifield and William R. Miller, Southington.

ILLINOIS.

Personal.—Dr. Stephen V. Balderston has been appointed health commissioner of Evanston, vice Dr. William R. Parkes, resigned.——Patients of Dr. John B. Hench, Hinsdale, on Thanksgiving Day, which was also the twenty-fifth anniversary of Dr. and Mrs. Hench's wedding, showed their appreciation by presenting them with a chest of silver.——Dr. and Mrs. Frank A. Phillips, Chicago, are spending the winter in Arizona.——Dr. Arthur F. Beifeld and Dr. and Mrs. Milton K. Eisenstaedt, Chicago, have gone to Europe.——Dr. Otto T. Freer, Chicago, has returned from Europe, where he demonstrated his septum operation in clinics at London, Edinburgh, Berlin, Vienna, and other cities.

Cost of State Wards.—In a statement prepared by William C. Graves, secretary of the State Board of Charities, the average per capital cost in the seventeen charitable institutions of the state for the quarter just ended was $43.19. The figures for the individual institutions were as follows: Hospitals for the Insane: Southern Hospital, Kankakee, $29.23; Central Hospital, Jacksonville. $33.03; Southern Hospital, Anna, $33.30; Northern Hospital, Elgin, $64.55, and General Hospital, Watertown, $38.61, and Criminal Asylum, Menard, $42.15. Institution for Feebleminded, Lincoln, $37.11; School for Deaf, Jacksonville, $40.19; Girls' School, Geneva, $44.83; Boys' School, St. Charles, $54.96; School for Blind, Jacksonville, $68.42; Orphans' Home, Normal, $71.07; Soldiers' Home, Quincy, $32.74; Widows' Home, Wilmington, $67.14, and Industrial Home for Blind, $77.60.

Chicago.

Tuberculosis Hospital.—The construction work on the new million dollar tuberculosis hospital for Cook County will begin in a few days. The building permit has already been procured.

Surgeons Give Operating Room.—The surgeons of the staff of the Columbus Hospital have made a substantial donation to the institution by contracting to equip an operating room at a cost of more than $5,000.

New Contagious Hospital Opened.—The new City Hospital for the Treatment of Contagious Diseases opened November 28, with four patients suffering from diphtheria. Dr. Margaret M. Jones has been appointed physician in charge. The capacity of the hospital is about 200. Only cases of diphtheria and measles will be received in the institution.

November Mortality.—The deaths during November were 2,425, 144 more than for the preceding month; and 206 more than for the corresponding month of 1907, the respective annual death rates being 14, 12.41 and 12.81 per 1,000. Chief among death causes for the month were tuberculosis, with 303 deaths; pneumonia, with 275; heart diseases, with 225; and nephritis, with 200.

Contagious Diseases.—During the week ended December 5, 778 cases of contagious diseases were reported to the Department of Health, distributed as follows: Diphtheria, 192; scarlet fever, 183; measles, 102; chickenpox and tuberculosis, each, 93; typhoid fever, 52; pneumonia, 28, and whooping cough, 9. There was a decrease in all contagious diseases, excepting typhoid fever, which increased 8 during the week.

Fined for Violation of Ordinance.—Drs. Bernard DeKoven and Alexander A. Whamond are said to have each been fined $10 and costs, November 24, for failing to report cases of epidemic diseases to the commissioner of health. For a similar offense. Dr. Peter T. Burns is said to have been assessed costs of $7.75. Martin and Minnie Rudd were fined costs for permitting a child infected with contagious disease to break quarantine.

Hospital Pavilion Opened.—The private pavilion of the Presbyterian Hospital, completed at a cost of $390,000, was formally dedicated November 29. Albert M. Day, president of the hospital, delivered the dedicatory address, and an address was also made by Dr. Frank Billings. The new wing contains 58 private rooms and will accommodate 75 patients. A feature of the building is a sun parlor, the roof and one-half of which is enclosed in glass, so that patients may enjoy the sun in any kind of weather.

Deaths of the Week.—The deaths from all causes during the week ended December 5 were 520, the same number as for the preceding week and 26 fewer than for the corresponding week of last year. This is equivalent to an annual death rate of 12.52 per 1,000. Pneumonia, for the first time this winter, takes the place of highest mortality, with 87 deaths, followed by heart disease, with 57; tuberculosis, with 49; nephritis, with 41; acute intestinal diseases, with 38; violence (including suicide), with 29; cancer, with 23; diphtheria and nervous diseases, each with 20; typhoid fever, with 6; scarlet fever, with 9; and influenza and measles, each 2 deaths.

MARYLAND.

New Hospital.—Through the efforts of Dr. Howard Bratton, Elkton, president of the Board of Health of Cecil county, a hospital has been equipped and opened at Elkton, with accommodation for 26 patients, at an expense of $25,000.

Illegal Practitioner Found Guilty.—George M. Fisher, indicted by the grand jury for engaging in the practice of medicine without being registered, is said to have been found guilty by a jury at Hagerstown, November 24. Notice of appeal was immediately filed by his counsel.

Antituberculosis Association.—An antituberculosis association was organized for Montgomery county at Rockville, November 24, at which H. Wirt Steele, secretary of the state association, delivered an address on "How to Stamp Out Tuberculosis." Joseph E. Janney was elected president and S. F. Prettyman, secretary of the association.

Gift for Sanatoria.—Mrs. George H. Beckwith, Catonsville, has offered two tracts of land, valued at $100,000, one at Saranac Lake, N. Y., and the other at Aiken, S. C., to the United States Government for the erection of sanatoria for the poor suffering from tuberculosis. Mrs. Beckwith is endeavoring to obtain an appropriation from Congress for the erection of buildings on the tract of land at Aiken.

Society Meetings.—At the annual meeting of the Medical Society of Frederick County, held in Frederick, November 11, Dr. Arthur H. Hawkins, Cumberland, councilor for the district, spoke on "The Best Means of Having Largely Attended and Profitable Meetings of County Societies by Means of Postgraduates Courses and Carefully Reported Clinical Cases," and stated his belief the instruction afforded in this way would gradually draw all eligible physicians to join the organizations and remain in them from motives of self-interest. He instanced the work accomplished in this way in the Allegany County Medical Society and the different feeling engendered. The following officers were elected: Dr. Thomas C. Routson, Buckeystown, president; Drs. H. Slicer Hedges, Brunswick, and Charles F. Goodell, Frederick, vice-presidents; Dr. Franklin B. Smith, Frederick, secretary; Dr. Wilson A. Long, Frederick, treasurer; Dr. Charles H. Conley, Adamstown, censor, and Dr. Ira J. McCurdy, Frederick, delegate to the Medical and Chirurgical Faculty of Maryland.——At the annual meeting of Queen Anne County Medical Society, held recently, Dr. William G. Coppage, Church Hill, was elected president, and Dr. Ernest F. Smith, secretary.

Baltimore.

Grenfell in Baltimore.—Dr. Wilfred T. Grenfell of Labrador will be a guest of Dr. Henry M. Hurd in Baltimore, December 15 and 16, and will make several addresses on the subject of his work in Labrador.

Society Election.—At the annual meeting of Baltimore City Medical Society, held December 1, the following officers were elected: President, Dr. Jacob H. Hartman; vice-president, Dr. William D. Booker; secretary, Dr. William E. Magruder; treasurer, Dr. William S. Gardner, and censor, Dr. Randolph Winslow.

Personal.—Dr. Peregrine Wroth, Jr., resident physician at the Union Protestant Infirmary, has resigned and entered practice at Hagerstown. He will be succeeded by Dr. Richard P. Bell, of Staunton, Va. Dr. Harry L. Homer has been made first assistant and Dr. Arthur H. Morse, second assistant; Drs. James H. Scarborough and J. P. Fletcher have been appointed surgical internes and Dr. J. E. Barnes, Charleston,

W. Va., has been appointed medical interne at the institution. ——At the annual meeting of St. Andrews' Society November 30, Dr. George A. Fleming was elected president and Dr. G. Lane Taneyhill and Dr. Thomas L. Shearer were elected physicians.

MASSACHUSETTS.

The Smallpox Situation.—The smallpox situation in Springfield remains practically unchanged, and there are still about twenty-five families under quarantine.

Staff for Crippled Children's Home.—At the annual meeting of the New England Peabody Home for Crippled Children, Drs. Robert W. Lovett and Robert Souter were chosen attending surgeons; Dr. Henry H. Hitchcock, attending physician; Dr. Leon W. Mansur, oculist; and Drs. Abner Post, John H. McCollom, Albion S. Whitmore and Edwin B. Kellogg, consulting physicians.

Infectious Diseases.—There were reported to the State Board of Health during October the following infectious diseases: Diphtheria, 1,371 cases; tuberculosis, 593; scarlet fever, 592; typhoid fever, 405; measles, 321; whooping cough, 75; varicella, 64; cerebrospinal meningitis, 10; erysipelas, 3; rabies, 3; tetanus, 2; mumps, 2; ophthalmia neonatorum, 1; and malignant pustule, 1.

October Deaths.—During October, there were reported to the State Board of Health 3,294 deaths. Of these 1,114 were of children under 5 years of age; 986 were from the principal infectious diseases; 262 from acute lung diseases; 275 from phthisis; 67 from diphtheria; 42 from typhoid fever, and 8 from measles. During the month there were also reported 9 deaths from cerebrospinal meningitis, 5 from scarlet fever, 13 from whooping cough, 4 from meningitis, and 1 each from influenza, smallpox, tetanus, anthrax and glanders.

Personal.—Dr. Carl L. Alsberg has resigned his position in the department of physiological chemistry in Harvard Medical School, to take charge of the poisonous plant investigation in the bureau of plant industries of the United States Department of Agriculture.——Prof. W. B. Cannon has been elected president; Dr. J. L. Brenner, secretary, and Dr. Frank B. Mallory, treasurer of the Boston Society of Medical Sciences.——Dr. George W. Dow, Lawrence, has been reappointed medical examiner and Dr. Victor A. Reed, Lawrence, has been appointed assistant medical examiner for the Fifth Essex District.——Dr. Joseph Santosuosso, Boston, a member of the common council, has been admitted to the bar and expects to devote himself to the law, dropping his medical practice.——Dr. Anson C. Peckham has resigned as a member of the staff of Union Hospital, Fall River.

NEW JERSEY.

Society Meetings.—The Clinical Society of the Oranges was recently organized, with six charter members, for the study of therapeutics, clinical medicine and surgery. Dr. Leonard H. Smith, East Orange, was elected president, and Dr. Charles W. Buvinger, East Orange, secretary-treasurer.——Middlesex has organized what is said to be the first county District-School Physician's Association in the United States, of which Dr. Henry D. Van Zandt, Jamesburg, has been elected temporary chairman, and Dr. Edwin I. Cronk, New Brunswick, temporary secretary.——The annual meeting of the Ocean County Medical Society was held recently in Lakewood, when Dr. William G. Schauffler, Lakewood, was elected president; Dr. Otto C. Thompson, Cassville, vice-president; Dr. Alexander M. Heron, Lakewood, secretary; Dr. Irwin H. Hance, Lakewood, treasurer, and Dr. Vanderhoef M. Disbrow, Lakewood, delegate to the state medical society.——At a meeting of the Tri-County Medical Society, comprising the counties of Salem, Gloucester and Cumberland, held in Bridgeton, October 28, the following officers were elected: President, Dr. Henry B. Diverty, Woodbury; vice-presidents, Drs. Richard M. A. Davis, Salem, and Walter P.Glendon, Cedarville, and secretary-treasurer, Dr. George E. Reading, Woodbury.——The tenth annual meeting of the Tri-County Medical Association, comprising the counties of Morris, Sussex and Warren, was held in Washington, October 13, when the following officers were elected: President, Dr. Jackson B. Pellett, Hamburg; vice-presidents, Drs. James Douglas, Morristown, and James M. Reese, Phillipsburg; secretary, Dr. Charles B. Smith, Washington; treasurer, Dr. Frederick W. Flagge, Rockaway; and executive board, Drs. Bruno Hood, Newton, Stephen Pierson, Morristown, and Frank W. Curtis, Stewartsville.——At the annual meeting of the Washington Medical Society, Dr. Charles B. Smith was elected president; Dr. Frank P. McKinstrey, vice-president; Dr. Thomas S. Dedrich, secretary; Dr. George C. Young, corresponding secretary; and Dr. Charles M. Williams, treasurer.——The Practitioners' Society of East Monmouth, at its annual meeting held in Redbank, elected Dr. Joseph T. Welch, president; Dr. George H. Baker, vice-president; Dr. Edward M. Beach, secretary; and Dr. William K. Campbell, treasurer, all of Long Branch.

NEW YORK.

Hospital Bed Endowed.—Mrs. Russell Sage has completed an endowment of $5,000 for a bed in the Nassau Hospital at Mineola, L. I., in memory of a friend.

Another X-Ray Victim.—Dr. Fred D. Andrew, Rochester, radiologist of the Rochester City Hospital, was obliged to have his left hand amputated December 4, on account of disease due to frequent exposure to the *x*-ray.

Personal.—Dr. Warren B. Andrews, Newburgh, has resigned as physician of the City and Town Home and of the Children's Home.——Dr. Don M. Hooks, Binghamton, has been appointed coroner of Broome county.——Dr. William Hollinger, Newburgh, was thrown from a carriage in a runaway accident, November 19, but escaped serious injury.

No Fear of Milk Famine.—Although the milk supply has been curtailed on account of quarantining cattle afflicted with the foot and mouth disease there is no immediate danger of a milk famine. In the opinion of the health board officials there is no danger of the milk supply becoming infected from this source. Inspectors are keeping close watch and call for the immediate killing and burning of all cattle having the disease, and it is believed that the disease will be quickly exterminated. The slaughter of infected animals was begun November 21 in thirteen localities in the western part of the state. Even shipments coming to New York City under bond, consigned to foreign ports, have been held up and in some cases the government has ordered the killing of cattle.

To Safeguard Medical Research.—The Medical Society of the State of New York has issued the following letter to the practitioners of medicine of the State of New York:

> The Society for the Prevention of Abuse in Animal Experimentation last year caused to be introduced into the Legislature of this State a bill seriously restricting experiments on living animals. The above named society now enters the field again and proposes another bill of the same general character as that of last year. The Medical Society of the State of ——————, through its committees on legislation and experimental medicine, successfully opposed the passage of last year's measure. Acting under the resolution referring to animal experimentation, which was passed at the last annual meeting of the state society, its committees on legislation and experimental medicine will oppose the passage of the proposed bill. We, therefore, urge all members of the medical profession to disapprove the measure and on its introduction into the legislature, to work in all legitimate ways for its defeat. Specific objections to it will be presented later.

The letter is signed by Drs. Frank Van Fleet, chairman of the Committee on Legislation; Joseph D. Bryant, chairman of the Committee on Experimental Medicine; and John G. Curtis, secretary of the Committee on Experimental Medicine.

New York City.

Personal.—Dr. Charles L. Dana returned from Europe November 30.——Dr. Rufus I. Cole, Johns Hopkins Medical School, Baltimore, has been appointed director of the hospital of the Rockefeller Institute for Medical Research and Dr. Christian A. Herter, physician to the hospital.——Dr. S. Irving L. Roome, Stapleton, is said to be in a critical condition in the S. R. Smith Infirmary, from the effects of an overdose of morphin.

Brooklyn's Jewish Hospital.—This hospital, which was opened in December, 1906, has had during the past year 2,720 applicants for admission, which is an increase of 60 per cent. over the previous year. The dispensary consultations numbered 19,152, an increase of 61.5 per cent. It was stated that two new wings were needed and that the training school has grown so rapidly as to make additional equipment imperative. The hospital is entirely supported by subscription.

The Red Cross and Tuberculosis.—At the annual meeting of the New York branch of the American National Red Cross it was announced that the camp at Schenectady would be reopened in the spring. The camp which is to be opened in the roof of the Vanderbilt Clinic has received $5,000. The clinic has fitted up the roof at a cost of $10,000 and will furnish the physicians. When this camp is fully equipped it will care for more than one hundred patients. Christmas stamps are being sold to support this work. The stamps were recently pictured and described in The Journal.

The Dam Builders' Model Camp.—Frequently in doing the work on the conduits for the water supply of New York City the camps for the workers have been a menace to the health of the community, but in building the dam near Esopus, which is to set back the waters of the Esopus and form the great Ashokan reservoir to furnish the future water supply of New York City, a model camp has been established. Camp City is a camp in name only, being equipped with sewers, water mains, a modern sewage disposal camp and many up-to-date educational advantages both for children and adults.

Proposal to Abet Charity Abuse.—There is a rule at Bellevue and the Allied Hospitals which makes it permissible to charge a patient who has in his possession more than $50 when he is admitted, $1.50 a day. Coroner Harburger says that this is confiscation of other people's money and is contrary to the provisions of the hospital charter. In consonance with this view he has prepared a bill which will be introduced at the coming session of the legislature in Albany to the effect that all patients who reside in the City of New York and are admitted for treatment to Bellevue and Allied Hospitals of the City of New York shall be admitted free of all charge, and if the patients have money in their possession, none of it shall be taken from them and charged to treatment. Dr. Brannan, president of the board of trustees of Bellevue and Allied Hospitals, states that the rule to which Dr. Harburger objected, had been adopted on the advice of the corporation counsel, in order to prevent persons who were able to pay from obtaining free treatment.

Buffalo.

Fee for Reporting Contagious Diseases.—The State Commissioner of Health is said to have made a ruling that physicians reporting cases of contagious diseases are entitled to a fee of $1 for each case reported.

Roswell Park's Jubilee.—This year marks the twenty-fifth anniversary of Dr. Roswell Park's professorship in the University of Buffalo. In commemoration of the event a dinner was tendered him December 7, in the Hotel Iroquois, by the medical profession of Buffalo, as an expression of their appreciation of Dr. Park as a teacher and of his ability as a surgeon.

Personal.—Dr. Dewitt G. Wilcox is about to remove to Boston.——Dr. Francis E. Fronczak, assistant health commissioner, and also commissioner of health in the town of Cheektowaga, was assaulted by some resentful tenants whose houses he was obliged to quarantine. He swore out warrants for six of his assailants who were tried before a justice of the peace and sentenced each to thirty days in the penitentiary without option of fine.

OHIO.

Library for County Physicians.—Quarters have been secured for the library of the Richland County Medical Society in the Municipal Library Building, Mansfield, where medical books and journals are to be kept in easy access of physicians and out of the reach of the general public.

Personal.—Dr. John F. Jones, Columbus, has succeeded as jail physician, Dr. John F. Hane, recently chosen coroner of Franklin county.——Dr. Charles A. Stephens, Helena, sustained serious injuries November 20, by the overturning of his automobile.——Dr. W. B. Tracy, Newark, has been appointed assistant physician at the Athens State Hospital for the Insane.——Dr. David G. Sanor has been chosen chief of staff of Mercy Hospital, Columbus, vice Dr. Schueller, resigned.——Dr. and Mrs. Hanson P. Shelton, Georgetown, sailed for Europe, November 28.

Cincinnati.

Non-Partisan Board of Health.—The Cincinnati Academy of Medicine, the Ministerial Alliance, the City Club, and associated organizations, have endorsed a resolution to establish a non-partisan board of health separate from the board of public service, and to be appointed by the mayor.

Personal.—Dr. Charles A. L. Reed has had conferred on him the cross of the Legion of Honor of France.——Dr. Samuel E. Allen was thrown from his buggy in a collision with an automobile recently, and was seriously injured.——Dr. Robert Mussey, interne in the City Hospital, was operated on November 19, for appendicitis.——Dr. Charles L. Bonifield was struck by his own automobile several weeks ago and sustained a fracture of the fibula.

Defective School Children Segregated.—One hundred and fifty children of the public schools of Cincinnati who are four years or more behind on their studies, have been segregated in one school and are to be examined by the following corps of specialists who have volunteered their services: Diseases of the eye—Drs. Frank B. Cross, Walter Forchheimer, William H. Campbell, Wylie McL. Ayres, Louis Stricker, and Albert E. Hussey; diseases of the ear—Drs. Walter E. Murphy, Samuel Iglauer, William Mithoefer, Clayton B. Conwell, and William C. Harris; nervous diseases—Drs. David I. Wolfstein and Philip Zenner. Dr. Marian Schaar will investigate the environment of the children outside of school hours and Drs. Mark A. Brown and Louis Maloney will make such physical examination as may be required.

PENNSYLVANIA.

School Surrenders Charter.—A petition has been filed by the stockholders of the Western Pennsylvania Medical College, Pittsburg, asking permission to surrender all powers contained in its charter and for a dissolution of its corporation. The petition states that the corporation has sold and conveyed to the University of Pittsburg all its real estate, equipment and physical assets.

Cattle Disease No Longer a Menace.—The State Live Stock Sanitary Board, November 25, received reports which indicate that the epidemic of foot and mouth disease among cattle is under control. It has been recently learned that many of the alleged cases reported to the veterinary officers have. been erroneous. The state health commissioner has sent a letter to each of his county medical inspectors, 733 health officers, and other field men, instructing them to give all aid in their power in the fight against the disease.

Personal.—Dr. Harry M. Wasley has been appointed director of the State Dispensary for Tuberculosis at Shenandoah.——Dr. William P. Painter, Darby, fell down stairs at his home, November 25, and is still confined to his bed.——Dr. William T. Davis, first assistant at the State Hospital, Fountain Springs, is reported to be seriously ill at that institution.——Dr. H. Herbert Herbst has been elected mayor of Allentown.——Dr. Frank G. Bryant, Scranton, has been appointed special medical inspector in charge of the scarlet fever situation.——Dr. James L. Jamison has been made health officer of Wrightsville.——Dr. and Mrs. Claude W. McKee, Scottdale, sailed for Europe November 28.

Typhoid Fever in Reading.—Typhoid fever is still on the increase in Reading. On December 4, 62 new cases were reported, and on December 5 27, thus making a total reported thus far of 529. The State Health Commissioner has been asked by the local Board of Health to take charge of the situation. Dr. Dixon has already responded by sending his chief sanitary engineer, with twenty-five trained inspectors and also chief state medical inspector, Dr. Arthur B. Moulton, with a corps of nurses, under the supervision of Miss Alice M. O'Halleran. The water and milk supply of the city have been diligently investigated by the sanitary inspectors, but thus far the source of contagion has not been discovered. All houses containing typhoid fever patients are placarded, and notices asking the residents to boil all drinking water, have been distributed throughout the city.

Philadelphia.

Entire Resident Staff Dismissed.—Troubles which have persisted for nearly a year at St. Agnes Hospital are said to have culminated, December 1, in the dismissal of the entire resident staff for "inefficiency and insubordination."

Personal.—Dr. H. Conrad Egly, former assistant surgeon of the Mexican Central Railroad at Aguas Calientes, Mexico, has been transferred to take charge of the emergency car at the Culican front of the C. R. Y. & P. Railroad, Sinaloa.——Dr. S. Ira McDowell sailed for England November 28.

Gift to Hospital.—The hospital of the Woman's Medical College of Philadelphia has recently received as a gift from several individuals the furnishing of five private rooms. In addition to this, the hospital received, as the result of a fraternity entertainment, $310, which will be used in furnishing two new rooms in the hospital, the surplus being employed as the management may see fit.

SOUTH CAROLINA.

Physician Not Guilty.—In the case of Dr. William L. Linder, Union, charged with shooting a negress who had previously made an attempt on his life last November, the jury returned a verdict of not guilty, holding that the shooting was in self-defense.

Medical College Opens.—The Medical College of the State of South Carolina, Charleston, opened October 1, with the largest enrolment in the history of the institution. In the absence of Dr. George Wilson, dean of the college, Dr. Lane

Mullally welcomed the students. Dr. Charles M. Reese, the new professor of general surgery, also addressed the students. The college has spent about $3,500 in the enlargement of the laboratory, which has nearly trebled its floor space.

Conference on Pellagra.—On October 29, a conference on pellagra was held at the State Hospital for the Insane, Columbia, at which a number of physicians from North Carolina, Georgia and South Carolina were present. A large proportion of the papers read were devoted to the causation of pellagra, the maize theory and the germ theory each being considered. The board of regents of the state hospital passed resolutions directing the attention of the state board of health to the necessity of placing the whole problem of pellagra in the hands of expert pathologists and bacteriologists. A committee was appointed to arrange for the publication and distribution of the transactions of the conference, and a second committee to decide whether or not it is advisable to form a society in the South Atlantic and Gulf States for the study of tropical diseases.

TENNESSEE.

New Clinic Opened.—Tennessee Medical College, Knoxville, has established a free clinic, to be opened daily from 1:30 to 3 p. m. A general reception room has been arranged, and also a number of smaller rooms for the treatment of the different classes of diseases.

Tuberculosis Dispensary.—Arrangements have been made by the Centennial Club of Nashville to establish a free dispensary for indigent consumptives. A room is to be made ready on the third floor of the building occupied by the health department, where these patients may obtain medicine, advice and aid.

Commencement Exercises.—The commencement exercises of the Medical Department of the University of the South, Sewanee, were held October 27, when a class of 36 was graduated. Dr. John S. Cain, dean of the medical department, made the doctorate address, and the diplomas were awarded by the vice-chancellor, B. Walton Wiggins.

Personal.—The following physicians have been elected directors of the Knoxville Association for the Prevention and Relief of Tuberculosis: Benjamin D. Bosworth, Henry P. Coile, Albert G. Kern and Ernest R. Zemp.——Dr. John Overton has succeeded Dr. E. E. Reismann, resigned, as house surgeon of the Nashville City Hospital——Dr. Benjamin F. Turner, Memphis, has been appointed a member of the city park commission.——Dr. H. M. Boswell, interne in the Nashville City Hospital, has resigned.

WASHINGTON.

Compulsory Vaccination.—The enforcement of the order of the school board that all children should be vaccinated before November 9, caused 1,647 unvaccinated children on that day to be sent home from the public schools of Seattle.

Mulcted for Unauthorized Autopsy.—The jury in the case of Joseph Beeman against Dr. Marion F. Setters, Spokane, charged with performing an illegal autopsy January 4 last, is said to have returned a verdict for the plaintiff, allowing him $1,000 damages. The amount of damages claimed was $10,000.

Personal.—Dr. Robert L. Maloney has been appointed health officer of Anacortes, vice Dr. Frederic S. Sandborg.——Dr. A. Jefferson Nelson has been appointed assistant medical inspector of Ballard, vice Dr. H. P. Heliker, resigned.——Dr. Ernest L. Bickford, Seattle, has returned after a year abroad.——Dr. Henry J. Fleischer, Seattle, has been taken to the Portland Sanatorium for treatment.——Dr. John Nywening is announced as the next health officer of North Yakima.

WISCONSIN.

Epidemic Diseases.—On account of an epidemic of smallpox, the churches and schools of Manitowoc were closed November 22 and fifty houses are under quarantine.——The schools of Green Bay were closed November 25, on account of the prevalence of diphtheria. It is estimated that there are now more than 25 cases in the city.

Personal.—Dr. E. Clayton Pratt, Milwaukee, has been appointed assistant surgeon to the Wisconsin Veterans' Home.——Dr. Charles L. Sonnemann, Milwaukee, was held up, November 12, and robbed of a gold watch.——Dr. Maurice D. Bird has succeeded Dr. George F. Colter as president of the Menominee River Hospital, Marinette.——Dr. Edward Spegelberg, house physician at the Emergency Hospital, Milwaukee, has resigned and will enter private practice in Wausau.——Dr. Ulysses M. Horswell, Wausaukee, has succeeded Dr. William R. Bell, resigned as health officer. After a course of study at Rochester, Minn., Dr. Bell expects to go abroad for two years or more.

GENERAL NEWS AND COMMENT.

Surgeons and Gynecologists to Meet.—The twenty-fourth annual meeting of the Southern Surgical and Gynecological Association will be held in the Planters' Hotel, St. Louis, December 15, 16 and 17, under the presidency of Dr. Frederick W. Parham, New Orleans. Dr. John Young Brown is chairman of the committee on arrangements.

Sanatorium for Printers in Arizona.—The International Typographical Union, which maintains a home for sick and aged printers in Colorado, is about to establish a tuberculosis tent sanatorium for its members in Arizona.. At the recent meeting of the union, $10,000 was appropriated for the establishment of the tent sanatorium, not more than one-half of which is to be used for construction of headquarters.

Society Meeting.—At the annual meeting of the Ohio Valley Medical Association, held at French Lick Springs, Ind., November 11, 12 and 13, the following officers were elected: President, Dr. Curran Pope, Louisville; vice-presidents, Drs. Albert E. Sterne, Indianapolis; G. Frank Lydston, Chicago; and Earl Harlan, Cincinnati; and secretary-treasurer, Dr. Benjamin L. W. Floyd, Evansville, Ind. Evansville was selected as the place for the next annual meeting.

Gorgas Starts for Chile.—Col. William C. Gorgas, president of the Isthmian Canal Commission, sailed for Valparaiso, Chile, from La Boca, November 23. Colonel Gorgas has been appointed one of the ten delegates from the United States to the Pan-American Scientific Congress to meet at Santiago, Chile, Christmas Day, and will present a paper on "The Control of Yellow Fever in the Tropics." Dr. Pedro Obarrio, superintendent of Santo Tonas Hospital, Panama, delegate from the Republic of Panama, sailed on the same steamer.

Cholera in the Philippines.—During the week ended September 26, there were 314 cases of cholera, with 184 deaths, in the city of Manila, and during the same week 1,122 cases, with 745 deaths, were reported from the provinces. During the succeeding week, 67 cases of cholera and 33 deaths were reported from Manila and 1,666 cases, with 977 deaths, from the provinces.——On account of two cases of cholera having occurred on the U. S. Army transport *Sheridan*, the steamer was disinfected and held in quarantine for seven days.

Plague Prevention Work.—Passed Assistant Surgeon Rupert Blue, P. H. and M.-H. Service, reports that the last case of plague in San Francisco was reported January 30; that during the week ended November 14, 11 sick and 103 dead were inspected, no case of plague being found; and that 1,352 rats were examined bacteriologically, no plague-infected rats being found. At Oakland and Port Richmond for the previous week no plague-infected rats were found. The reports from Los Angeles, Cal., and Seattle, Wash., regarding the examination of rats for plague infection, produce similar negative results.

Antityphoid Immunization Approved for Army.—The board of medical scientists, composed of Surgeon-General Robert M. O'Reilly, Drs. Victor C. Vaughan, Ann Arbor, William T. Councilman, Boston, John H. Musser, Philadelphia, Alexander Lambert and Simon Flexner, New York City, and William S. Thayer, Baltimore, which met at the War Department, December 7, and considered the advisability of immunizing soldiers against typhoid fever by vaccination, recommended that the method be adopted in the United States Army, and issued the following statement: "The board is convinced of the usefulness and harmlessness of antityphoid vaccination, and recommends that the practice of voluntary vaccination be introduced in the Army of the United States as a practicable means of diminishing the extent of typhoid fever."

The Canal Zone.—The report of the sanitary department of the Isthmian Canal Commission for September shows a sick rate of 25.09 per 1,000, which compares favorably with the rate of 27.28 for 1907, and of 37.74 for 1906, and is lower than the rate for August, which was 25.24 per 1,000. This means that comparing September, 1908, with September, 1906, there has been a saving in the working force of 16.200 days of illness. The death rates show a similar improvement. In September, 1905, the rate was 33.52 per 1,000; in September, 1906, 57.34 per 1,000; in September, 1907, 28.63 per 1,000; and in September, 1908, 12.78 per 1,000.——Of the 19 deaths of whites during the month, 12 were due to violence, while of the 29 deaths among negroes, 5 were due to this cause.

The death rate for white employés for September was at the annual rate of 18.43 per 1,000, and that for colored workmen, 10.65. There has been a marked decrease in the cases of malaria for September. In September, 1907, there wer 1,811 cases of malaria among employés; in August, 1908, 1,525; and in September, 1,410.

Newspaper Publishes Retraction.—The suit brought by Dr. S. Adolphus Knopf, New York City, against the Philadelphia *North American*, which on May 7, 1907, misquoted an address delivered by Dr. Knopf, in which he was erroneously credited with saying that when a patient is dying of tuberculosis the physician should administer morphin in large doses so "that he may go painlessly and quickly," has been settled satisfactorily by a compromise, and in the *North American*, November 29, a retraction was published, and Dr. Knopf's statement, which had been misquoted, was correctly made as follows: "When we are in the presence of a dying consumptive, who is suffering, I believe it is our sacred duty to give him morphin to relieve his pains and make him comfortable, and let him die easy." It is understood that substantial damages have been paid Dr. Knopf, as well as reimbursement for his expenses in the suit, which has now been dropped, and also that the sum received for damages has been turned over by Dr. Knopf to the National Association for the Study and Prevention of Tuberculosis, to be used for the benefit of the consumptive poor, under the direction of the directors of the association. Dr. Knopf's friends are congratulating him on having pushed the suit to this satisfactory settlement, especially in view of the fact that the result indicates that physicians who are grossly misquoted, maliciously or otherwise, in the public press, may look for satisfaction in view of the injury thereby inflicted.

FOREIGN NEWS.

Fourth International Congress for Medical Electrology and Radiology.—The three preceding congresses were held at Paris in 1900, Berne in 1903 and Milan in 1906, and the fourth at Amsterdam in September, 1908. The permanent international committee includes C. Beck of New York, S. Leduc of Nantes, Bozzolo of Turin and Albers Schönberg of Hamburg, with Tripier of Paris as president and Oudin of Paris, Schiff of Vienna and Wertheim Salomonson as vice-presidents. The latter was president of the congress. The recent developments in precision registration of the movements of the heart by the string galvanometer rendered very timely Boruttau's address on the "Current of Action," the electric currents emanating from the heart muscle in action being the means by which the movements of the heart muscle are registered on the string galvanometer. Roentgen diagnosis showed great progress achieved since the previous meeting. The fulguration or lightning treatment of cancer was one of the interesting features of the congress. The exhibit of skiagrams, especially the stereoscopic Roentgen pictures exhibited, testified to the great strides in Roentgen diagnosis in the last three years, although the imperfections of all the measures for dosage of the rays at present in vogue were denounced by various speakers.

LONDON LETTER.

(From Our Regular Correspondent.)

LONDON, Nov. 28, 1908.

Compensation for Industrial Diseases.

The second report of the departmental committee on compensation for industrial diseases has been issued. It deals mainly with glassworkers' cataract and telegraphists' cramp. Dr. Legge, medical inspector of factories, has made an exhaustive inquiry with a view to determining the incidence of the former disease among glass workers. He examined the eyes of 513 persons exposed to the furnace glare in glassworks. He found that all classes of workers so exposed appear to suffer and that between the age of 30 and 40 opacities of one kind and another in the lens were about five times as frequent as in those engaged in other work; between 41 and 50, twice as frequent; and after 50, more than three times as frequent. Approaching the problem from the point of view of disablement comparison was made between 10,549 members of the Hearts of Oak Benefit Society in receipt of reduced sick allowance and 186 superannuated members of glass bottle societies. The percentage of cataract in the former was only .78, but in the latter it was 22.6. For many years the efficiency of the workman is little affected. Hence the difficulty of legislating for compensation. During the period of efficiency the workman can not claim that the disease has incapacitated him, and if the law required that half wages should be paid during the rest of the life of an artisan who had lost skill through cataract, employers might insist on a medical examination of the eyes and no employer would engage a man who showed incipient traces of the malady. Therefore, it is concluded that if the disease were scheduled like the other industrial diseases in the workmen's compensation act, the workpeople in the glass trade would lose more than they would gain. The committee recommend that when removal of the cataract becomes necessary, compensation should be made payable for a period not exceeding six months.

With regard to telegraphists' cramp, a proportion of those who use the Morse key instrument are found to be affected. The symptoms are pain, not confined to one group of muscles, spasm, tremor and weakness. The committee recommend that this disease should be considered as specific to the employment and subject to compensation.

Anglo-German Agreement as to Sleeping Sickness.

With view to the more effectual combating of sleeping sickness in the British and German possessions in East Africa, the two governments have agreed to take such steps as are practicable to prevent affected natives from passing into each other's territories. All such natives will be detained or segregated in the territory in which they are found. All natives will be prevented as far as possible from crossing from one territory into areas in the other which are declared infected. Segregation camps will be established at adjacent points of the boundary for the detention and care of affected natives. Crocodiles and other animals suspected of being a source of aliment to the glossina palpalis will be destroyed.

Cooperation Between Ministers and Physicians.

The movement which originated in Emmanuel Church, Boston, has spread to this country. The Pan-American Congress, which was held last summer, was attended, for the first time in the history of the Church of England, by delegates from all her dioceses and from the dioceses of all the churches in the world in communion with her. Church problems of all sorts were discussed, and at one of the meetings it was suggested that the clergy should study psychology in its relation to bodily disease. In the report which followed the proposition was submitted that bodily disease is a breach in the harmony of the divine purpose and is caused by want of moral harmony with the divine will. The suggestion was made that restoration of this harmony will often bring with it restoration of health. As a consequence the congress left behind it a heritage in the shape of the "Church and Medical Union," which was formed to promote cooperation of ministers and doctors in the healing of the sick. It has been alleged that the new movement is only a variant of what is called Eddyism, but it differs from the latter in not ignoring the physical aspect of disease and the medical profession.

PARIS LETTER.

(From Our Regular Correspondent.)

PARIS, Nov. 26, 1908.

The Nobel Prize.

Although the names of winners of the Nobel prize are always kept secret, some inkling always creeps out beforehand, if only because the winners, being obliged to go to Stockholm for the ceremony of the distribution of the prizes, are informed some months beforehand. It is already certain that the prize in medicine this year will go to Professors Metchnikoff, assistant director of the Pasteur Institute at Paris, and Ehrlich, director of the Institute of Experimental Therapeutics at Frankfort.

Resumption of the Courses of Anatomy at the Paris Medical School.

In view of the obstreperous conduct of the first and second year students, which prevented Professor Nicolas from giving his course (as mentioned in THE JOURNAL, Nov. 12, 1908, li, 1879, and Nov. 30, 1907, xlix, 1853), the dean posted notices at the entrance to the school stating that, if the students had complaints to make it was not through the daily papers that the dean ought to learn them, but through a delegation of those interested, which he was ready to receive. In response to this invitation, the students sent a delegation to express their wishes, among which was the assignment of a cadaver to each five students, instead of to each seven. The committee on instruction in practical anatomy has granted the chief demands of the students. There seems no excuse for continuing the agitation further; but the persons intriguing against Professor Nicolas have not given up. Fortunately, the Corporate Association of Medical Students has intervened. The majority have followed wise counsels, and now all is in order. The students who attend Professor Nicolas' class are less numerous than previously, but now they come to listen to him, while formerly they came to prevent him from speaking.

Deaths.

During the last few days, the medical profession has lost three members in high stations. Dr. Alix Joffroy, clinical professor of mental pathology and of diseases of the brain in the Paris Medical School, died suddenly from angina pectoris, aged 64. He was a modest savant, who had organized a sober and practical course of instruction at the Ste. Anne Asylum, where he had given his lesson the previous Saturday.

Dr. Hamy, one of our most remarkable anthropologists, has just died, aged 66. He took his doctor's degree in 1868, entered the Museum of Natural History of Paris in 1872, and from 1874 to 1887 had charge of numerous missions thence. He founded in 1880 the museum of ethnography of the Trocadero, of which he was curator, and which has made great growth. In 1882 he was named professor of anthropology of the museum, which post he held at his death. He was member of various learned societies—of the Society of Americanists, among others. In 1903 he was chosen associate at large of the Academy of Medicine.

Dr. Felizet, who died at 64, was formerly a surgeon of the hospitals of Paris and secretary general of the Surgical Society. He early began to specialize in surgery for children, and his treatise on "Inguinal Hernia in Children," is an authority on the subject.

BERLIN LETTER.

(From Our Regular Correspondent.)

BERLIN, Nov. 19, 1908.

Mortality from Puerperal Fever.

The puerperal mortality is still very high in Germany; in Prussia alone, in 1906, 3,722 women died of puerperal fever; of every 10,000 women living, 1.97 died, for every 10,000 deliveries about 29 died in childbed. The conditions are, strange to say, more unfavorable in the cities than in the country districts. Proportionately, the condition is most unfavorable in Berlin, where among 10,000 women delivered, 56.48 died in childbed, which is nearly twice the average for the whole of Prussia. These facts have for a long time caused the recognition of the necessity of improvement of the midwife system, as an important factor in the prevention of puerperal mortality. The number of midwives is also too small, especially in rural communities, where they find an insufficient livelihood, and the reliability of the midwives is often not equal to the requirements. Conditions will certainly be improved by the law passed this year in Prussia in regard to remuneration of midwives. The legal regulation of their fees brings the possibility of a more prosperous development for the profession of midwifery. The law establishes three categories of midwives: the "district midwives," on a salary; the midwives who are engaged by the authorities in charge of the indigent to give obstetric assistance to those needing help, and the midwives with independent practice. Moreover, a distinction is made between city and country midwives as their remuneration must be different in the large towns. In order that there may be a sufficient number of district midwives appointed for the rural districts, it is provided that the less well-to-do communities shall be assisted by financial aid from the state. A recent decree states that assistance of this sort shall as a rule be given only in districts that apply a definite part of their income from taxes to the support of midwives, and assure to the district midwife a definite income, either by granting a definite minimum salary, or by fixed supplements which shall reach this minimum sum when added to the income from practice. Also a free provision of instruments, apparatus, means of disinfection. etc.; assurance of compensation for interruption of business in consequence of infectious diseases, and, lastly, a definite provision in case of disability in the line of duty.

Tuberculosis Crusade.

It has been suggested to the Reichstag by some representatives of the national liberal party that the Reichstag shall request the federal government to lay before it as soon as possible a bill which shall extend the campaign against tuberculosis to the classes of the population which have so far been exempted from provision for care, especially by provision for more adequate financial resources and by legal regulations to insure proper disinfection of infected dwellings.

Medical Superintendence of Sanatoria.

Early in October the Prussian minister of education (Kultusminister) published an order involving the principles for the conducting of sanatoria by physicians: A responsible medical superintendent shall be provided for each sanatorium for the general care of the patients and for sanitary measures. In all large public sanatoria there must be a physician appointed to conduct the treatment of the patients, or a physician must be placed at the head of each department. In smaller public institutions, especially in smaller places, the permission may be extended to several or to all physicians to treat the patients referred to the sanatorium by them, or they may be called on for mutual assistance, provided that one physician stands responsible for the hygiene of the house, the training and supervision of the nurses, and other measures necessary for the general care of the patients. All institutions having more than 30 beds are included among the large sanatoria.

Sick Benefit Societies in Berlin.

The last annual municipal report gives information regarding the extent of the industrial insurance in Berlin. According to this the property of the societies amounts to about 17.600,000 marks ($4,224,000). The entire expenditures amounted to 32.700,000 marks ($7,748,000) in contrast to an income of 34,000,000 marks ($8,160,000). This was disbursed as follows: For medical treatment, 3,300,000 marks ($792,000); for medicines, 3,00,000 marks ($720.000); for indemnities to the sick, 11,600,000 marks ($2,784,000). About 3,500.000 marks ($840,000) were paid to the sanatoria for treatment and care. The number of workmen insured was about 730,000. There are 129 of these different industrial insurance societies in Berlin.

Popular and Juvenile Sports.

Following the praiseworthy example of America and England, sports have been fostered to a greater extent in Germany during the last few years, especially among the youth in schools. In this way for some time the introduction of popular and juvenile games has been favored and there are a number of successful results to show in this field. In a large number of communities playgrounds for the schools have been established, partly by the communal authorities and partly by societies. In a large number of cases the drill grounds have been placed at the disposal of the schools for this purpose by the military authorities. In about 500 grade and high schools a playtime obligatory on all pupils has been introduced in addition to the ordinary hours for gymnastics. In a large number of other schools such a regular playtime is optional. Also in a number of schools a regular system of outdoor sports is organized for the vacations. In a smaller way instruction in swimming and sport on the ice is favored in the schools. From all these measures it may be hoped that the growing youth will no longer, as has often formerly been the case, restrict its ambitions exclusively to mental training, but will also seek in addition a sufficient physical development so that the old proverb, "*Mens sana in corpore sano,*" may attain a higher significance for the youth of Germany.

VIENNA LETTER.

(From Our Regular Correspondent.)

VIENNA, Nov. 19, 1908.

Scarcity of Water in Vienna.

The remarkable weather conditions prevailing over central Europe since about July have caused an unprecedented fall in the daily water supply of Vienna. For a time much alarm was felt. Since the completion, in 1873, of the waterworks system, which usually brings over 26,000,000 gallons of pure, fresh mountain water daily to Vienna, typhoid fever has been practically limited to sporadic cases. [illegible] has reduced the daily flow of water to below [illegible] and the pipes supplying houses have had to be partially closed, causing much discomfort. There is, however, no danger to the public health, as all other sources of water were made useless many years ago.

Prophylaxis Against Infectious Disease.

A bill is proposed to require notification of the following diseases: Asiatic cholera, plague, smallpox, black water fever, typhoid fever, relapsing fever, leprosy, yellow fever, dysentery, scarlet fever, diphtheria, epidemic cerebrospinal meningitis, anthrax, glanders, hydrophobia and bites of animals suspected of rabies. The physician in the first place, then the midwife, nurse, owner of the hotel, inn or hostelry, teacher, landlord and coroner, are responsible for returning notification of any cases of such diseases coming to their knowledge. Any coercive measure is allowed by the law if the public health is endangered. Due compensation will be made for furniture or other property spoiled by disinfection, which is free of charge. Physicians at work during an epidemic are to receive a pension if they are incapacitated by the disease; their widows will be pensioned if death is caused thereby. The bill has no special provisions for vaccination, as a bill on that subject is to be brought in soon.

Pharmacology

THE INTERNATIONAL INSTITUTE.

Another Consumption Cure and Its Founder.

We have received from various sources inquiries relative to a Chicago concern known as the International Institute for the Treatment of Tuberculosis. Physicians have written saying that their patients have been approached by the agents of this "institute," and that the extravagance of the claims made for the "treatment" are equaled only by the exorbitance of the charges.

When we began to investigate the "International Institute" we found at the outset that its founder and ruling spirit and the "inventor" of its "treatment" was one Orlando Edgar Miller—an individual of whom we shall have something to say later.

THE TREATMENT.

In the booklet issued by the "Institute" we are informed that "this long looked for treatment and cure for tuberculosis is a combination of purely vegetable substances [which reminds one of the late lamented Lydia Pinkham] which, administered hypodermically, produces three effects on the system, viz.: Sleep, Relaxation, Elimination."

And there we have it. Not, of course, that we know much more about it now than we did before, but we know as much as a physician's limited knowledge of drugs makes it safe for him to know. For in the same booklet the reason given for not divulging the identity of this marvelous medicament is that physicians are "unacquainted with the actions of one of the drugs which we use and which is of recent origin, and is probably not used for any purpose by one physician in a thousand." Therefore, to conserve the interest of the patient's health—and incidentally the "institute's" finances—the world is going to be kept in ignorance of this, the great and only cure for tuberculosis. However, "when a sufficient number of physicians have acknowledged the results obtained, then the formula and methods of administration will be given to the medical profession." Meantime, bring along your phthisical patients and Orlando Edgar Miller, Ph.D., late professor of eugenics and sanitary science, late "dope" curist, late rupture curist, late numerous other things, will cure them, almost while you wait—for a consideration.

Incidental to the "hypodermics" there is rest and forced feeding and it would indeed be strange if some tuberculous patients when put to bed and given an abundance of nourishing food did not feel improved. Add to this, also, the psychic stimulation produced by the wildly extravagant promises of health, and we find sufficient reasons to account for any testimonials that may be obtained from patients in the early stages of this or any other "treatment."

WHAT THE "TREATMENT" COSTS.

When a prospective patient writes for information regarding the "cure" and its application, he is told:

> ". . . it would be impossible for this scientific treatment to be given anywhere else than in our hospital here in Chicago, or our sanitarium in Wisconsin."

Of the expenses to be incurred he is informed:

> "Our minimum charges are $25.00 per week as hospital expenses, and $250.00 as treatment fee. Of course, where cases are very seriously complicated, the price runs somewhat higher. Most persons in taking our treatment pay the $350.00 in advance. . ."

WHAT DOES IT PROMISE?

One may wonder *from* what class of patients this "Institute" will accept the minimum treatment-fee of $250. This question is answered in the pamphlet which is sent out to prospective victims:

> "QUESTION: What kind of cases do you accept?"
> "ANSWER: Any case with sufficient vitality to turn over in bed."

Evidently so long as the patient is not positively moribund, his money is acceptable. And what may the patient expect if he pays his money and takes the "treatment"?

> "QUESTION: What class of patients may hope for recovery?"
> "ANSWER: All may expect ultimate recovery excepting those who have serious complications below the diaphragm."

This "purely vegetable," "hypodermatic," "eliminative" treatment, therefore, ceases to be effective below the diaphragm. What such statements mean to the public—and what doubtless they are intended to mean—is, that any sufferer from laryngeal or pulmonary tuberculosis, no matter how near to death's door he may be, "may expect ultimate recovery" if he possesses money enough to take the O. E. Miller "treatment" and vitality enough "to turn over in bed."

THE INSTITUTE'S PERSONNEL.

The stationery of the International Institute has an imposing list of officers of the concern and of the members of its "medical department." In addition to having a Ph.D. (O. E. Miller) for president, it has an A.M. for treasurer, an LL.D. for secretary, while its counsel is no less a person than an ex-senator of the United States. As is the case with so many of these "institutes" the head of the concern is not a physician, and has, therefore, to hire men who are, to do his work. This, unfortunately, seems to have been easy of accomplishment, as we find the names of no fewer than seven physicians—four of Chicago, one of Milwaukee, and two of Indianapolis on the stationery as members of the "medical department"—to say nothing of an osteopath.

One of the Indianapolis members appears to have been drumming up trade for the "Institute," as we have received from physicians copies of a pamphlet which is being distributed, and whose title page reads as follows:

> THE TREATMENT OF TUBERCULOSIS.
> by
> JOHN T. SCOTT, M.D.
> INDIANAPOLIS, IND.
>
> Presented at the International Congress of Tuberculosis.
>
> WASHINGTON, D. C., OCTOBER, 1908.

Needless to say, the treatment referred to is that given by the International Institute. As for the paper being "Presented at the International Congress of [on?] Tuberculosis." the secretary-general of the congress informs us that the paper "was not on the program of the Congress and was not read in any of the sections. I have never seen this paper before."

That the concern intends to extend its operations is evidenced from the fact that the attempt has already been made. In the local newspaper report of the attempt to establish a "sanitarium" at Rome, Georgia, we read that the International Institute already has "a large sanitarium in Chicago," and that branches already "have been established in Wisconsin, Minnesota, Michigan and other localities are being selected."

O. E. MILLER AND HIS RECORD.

When any new treatment, for a well-nigh incurable disease, is advanced, physicians who are careful of their patient's safety and well-being first wish to know something about the individual responsible for it. Should this treatment be given to the world, not through the reputable channels of conservative medical journals, but by means of methods adopted by irregulars the world over, sensible physicians are still more insistent on examining the antecedents of those who originate it. Should such examination show that the "treatment" is essentially secret, that it is put on the market as a commercial proposition, and that it is originated by one who has no claim to medical training, the medical profession is more than justified in looking on such a proposition with suspicion. Should it be found, moreover, that the individual fathering the project is a man who has devoted a large part of his life to such concerns as "rupture cures" and fake sanitariums, and has at various times been arrested and has served at least some time in a federal prison—should all these things come to light, any sensible physician would naturally and rightly assume the attitude usually credited to Missourians—Show me!

For these reasons we give our readers some information regarding the president and originator of the International Institute—O. E. Miller, Ph.D.—which was incidentally acquired in our investigations of the "institute" itself.

According to the Chicago *Tribune*, June 11, 1902, Miller has been grocer, lawyer, newspaper editor, president of a Y. M. C. A., school superintendent, proprietor of a "rupture cure," and president of a "dope" sanitarium. He is now president of the "consumption cure" institute. Mr. Miller's long suit is his "piety." Throughout all the vicissitudes of his checkered career, though he has with remarkable versatility jumped from a "rupture cured or no pay" business to curing drug addicts "in from 6 to 8 days," yet he has ever demonstrated the value of religion as a financial asset.

THE O. E. MILLER "RUPTURE CURE."

In the early '90's Miller was running a "rupture cure" concern in Denver. So successful was this "cure"—in relieving the ruptured of their money—that within six years Miller claims to have done a business of over twenty million dollars. Branches of the concern were to be found in nearly every large city in the United States.

While pursuing this delectable business Miller was president of the "Professional Men's Debating Society" of the Y. M. C. A.; he also organized a large bible class and was carrying on what was known as the Cooperative Bible Union.

MILLER GOES TO PRISON.

While thus engaged in saving souls and curing rupture, Miller was convicted as an accessory to the misapplication of national banking funds and was sentenced to ten years in the federal prison at Fort Leavenworth, Kansas. After serving nearly two years of the sentence he was released on bond on the order of the Circuit Court of Appeals; the case then seems to have been dropped. Even in prison Miller's piety had to find expression and he established a Sunday school of which he was the leader and in addition he had charge of the music in the chapel on Sundays.

MILLER'S DYSPEPSIA "CURE" AND THE "ST. LUKE'S SOCIETY."

In 1898 O. E. Miller came to Chicago and, according to the *Tribune*, exploited a "medicated sand" treatment for stomach trouble and as a "sure cure for dyspepsia." In the meantime, he had, to use his own words, "come into possession of a very wonderful formula for the treatment of morphin, opium, tobacco and liquor habits." This was too good an opportunity to miss and he at once organized "a religious and philanthropic movement" known as the St. Luke's Society. This concern advertised that the patient would be put "into a normal condition" in "from six to eight days, in all cases of drug addictions where tobacco is not used. . . . Some forms of nervous affections require two weeks' time."

While a "philanthropic" movement, it did not give sufficient indications of being a charitable institution to warrant the Chicago Department of Health granting a license. The business was evidently a paying one, however, for Miller kept moving into more expensive and commodious quarters until finally he rented the old Hotel Woodruff as a "sanitarium." Then, when he had 150 persons in the building, came a fire in which thirteen inmates perished.

MILLER'S "UNIVERSITY AND SANITARIUM."

Miller's next venture was a combination *"university"* and "sanitarium," which he floated at Glen Ellyn, a suburb of Chicago. This institution was known as the "Ruskin University," though from the number of Millers in the published list of faculty members and officers, "Miller University" would have been more appropriate.

George McA. Miller, President; Ethics and Physiology.
Adalind D. Miller, Vice-President; English and Literature.
Orlando E. Miller, General Secretary; Eugenics and Sanitary Science.
Hamilton J. Miller, Treasurer.
Admer D. Miller, Mathematics.
Zoa L. Miller, Art.
Aurora L. Miller, Oratory.

Whether any or all of these numerous Millers were blood relations to Orlando E., or whether the combination was a mere nomenclatorial coincidence, we can not say.

AN ALL-EMBRACING COLLEGE OF MEDICINE.

The "university" very naturally had a college of medicine, and there was nothing narrow or hide-bound about it. According to the prospectus issued at the time:

> "Every student in the medical department of Ruskin University will receive instruction in *every known process of healing*, whether it goes under the name Regular, Irregular, Allopathic, Eclectic, Homeopathic, Physio-Medical, Osteopathic, Hydropathic, or any other title." [Italics ours.—Ed.]

But in spite of all the inducements held out to students, the "university" was not a financial success and had it not been for its "sanitarium" annex would have gone out of existence even sooner than it did. At the "Ruskin Sanitarium" were "drug addicts, nervous cases, rheumatic and kidney troubles successfully treated." The advertisements of this "sanitarium" also call attention to "The Famous Glen Ellyn Mineral Springs and Mud Baths." Inquiries fail to disclose the whereabout of either the famous springs or the equally noted mud baths. There are springs at Glen Ellyn, it is true, and as they are not of distilled water, there is doubtless mineral matter in them—hence, by poetic, or advertisers' license, mineral springs, if you please. There are, too, occasional swampy spots where, in wet weather, a person willing to risk arrest for indecent exposure, might take a mud bath—but the people of Glen Ellyn have never heard of any one taking that risk. An unfeeling town council finally got after Miller, and, as the papers stated at the time, fined him $100 and gave him ten days in which to leave the town.

THE INTERNATIONAL INSTITUTE.

Miller says: "Since severing my connection with the Ruskin movement, I have been engaged in one way or another in trying to get my treatment for tuberculosis to the attention of the medical profession." The "International Institute" was the result, of which Orlando Edgar Miller, Ph.D., is the president and William Bond Forsyth—of whom more later—vice-president and business manager.

THE CASE OF RAYMOND FORSYTH.

If this matter were being published simply and solely for physicians it would be needless to say more about it. The medical profession has seen so many much-vaunted "consumption cures" rise like a rocket and come down like a stick, that it is able to assign the "International Institute" to its proper place in the gallery of fakes. We are confronted with the fact, however, that the paid "cappers" and "steerers" for this concern are daily inveigling helpless but hopeful consumptives into taking its "treatment," and we are continually receiving letters from physicians asking what they shall tell their patients who enquire about this "institute." We are, therefore, investigating the cases of some of the patients who have received "treatment" at the hands of the "International Institute."

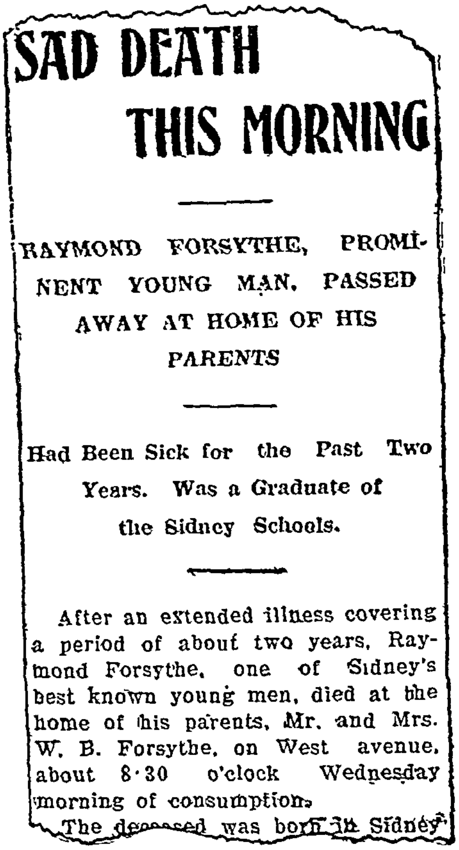
One case to which the concern gives such prominence as to publish it broadcast in pamphlet form as a "Case Report," is that of Raymond Forsyth. This young man was the son of the business manager of the concern, and the following information is given in the "Case Report" pamphlet:

> "Raymond Forsyth . . . had been examined by Dr. Frank Billings, Dr. Babcock and Dr. N. S. Davis, Jr., about a year ago. They all agreed he had a well-defined case of tuberculosis. . . ."

The young man was put on the O. E. Miller "treatment" with most marvelous (reported) results. The report closes as follows:

> ". . . has since gained 15 pounds of flesh; is getting stronger daily; walks and exercises by the hour.
>
> "His sputum has been examined weekly since his return and there have been found only slight traces of tubercle bacilli, which are gradually disappearing.".

Such is the information we get from the pamphlet. As a result of our investigations we could take up in detail various claims and statements and show their cruel mendacity, but probably the following reproduction from the Sidney (Ohio) *Daily News* of Dec. 2, 1908 will tell the tragic story more eloquently than anything we could say:



SAD DEATH THIS MORNING

RAYMOND FORSYTHE, PROMINENT YOUNG MAN, PASSED AWAY AT HOME OF HIS PARENTS

Had Been Sick for the Past Two Years. Was a Graduate of the Sidney Schools.

After an extended illness covering a period of about two years, Raymond Forsythe, one of Sidney's best known young men, died at the home of his parents, Mr. and Mrs. W. B. Forsythe, on West avenue, about 8·30 o'clock Wednesday morning of consumption.

The deceased was born in Sidney

As we have said, this young man's father, W. B. Forsyth, is vice-president, business manager, and, we understand, one of the principal stockholders in the "Institute." Yet the misfortune of a member of his own family is used as capital for "boosting" the business in which he is financially interested. Forsyth, senior, from all we can learn, has, like his associate Miller, been connected with more than one more or less shady concern. In his home town—Sidney, Ohio—he seems to be considered a "slick" individual who would not be deterred from going into any business because it happened to be only barely within the pale of the law. If we are correctly informed, he was some years ago mixed up in a concern known as the Bohemian Oats and Red Line Wheat Co., whose operations were such as to become the subject of enquiry by the courts. Forsyth also, it is said, exploited a wonderful "corn cure" for some years, later going into the oxygen business. Says a correspondent, "land schemes, irrigation schemes, patent car-coupler schemes and possibly others of greater or less notoriety can be charged up to this man, who thus makes capital out of his son's misfortune."

TWO MORE DEATHS.

Another case which was inquired into was that of a married woman from a small town in Illinois. The family physician, to whom we wrote, replied (Sept. 18, 1908) in part as follows, concerning the patient:

> "She is not there on my advice, but at the earnest solicitation of Mrs ————————, whose husband had tuberculosis and was there doing so nicely, improving every day, *but who was consigned to the grave yesterday*—cured I presume! . . . I am sure she will be in the Sanitarium Above within six months"

From a later letter (Nov. 26, 1908):

> "She [the patient] was brought home October 24, arriving here about 2 a. m. and died in her home about 11:45 a. m. of the same date"

Other cases are under investigation and but for the urgent need of giving physicians such facts as we have already at hand publication of this matter might have been further postponed. We shall publish in the future the results of such investigations if a continued pernicious activity of this concern makes it necessary.

Correspondence

The Viscosity of the Blood.

Columbia University, New York, Nov. 24, 1908.

To the Editor:—In The Journal, November 12, Dr. G. W. McCaskey has published a paper on the viscosity of the blood, taking especially into account its value in clinical medicine. I judge that Dr. McCaskey has not consulted a number of physiologic papers which have been published in recent years, and which, to a considerable degree, forestall his article.

Making no reference to the early and late work on the viscosity by Hürthle and myself, Dr. McCaskey has the kindness to refer to me in a footnote as follows:

"The following references may also be consulted: Burton-Opitz: *Am. Med.*, Phila., 1900, vii, 111; *Jour. Exper. Med.*, 1906, viii, 59, 240; *Abstr. Am. Med.*, new series, i, 42; *Arch. f. d. ges. Physiol*, cxii, 189." I am grateful to Dr. McCaskey for bringing my name so prominently before the readers of The Journal, but as I do not desire credit rightly belonging to others, I beg to state that I have not used *American Medicine* as a medium for publication.

Furthermore, in order to show how valuable the viscosity of the blood has appeared to a physiologist, and how widely many of the facts given in Dr. McCaskey's paper have been circulated prior to the publication of his article, I may be permitted to add the following references: Burton-Opitz: *Arch. f. d. ges. Physiol.*, 1900, lxxxii, 447-463 and 464-473; ibid, 1906, cxii, 1-5; ibid., 1907, cxix, 359-372; *Jour. Exper. Med.*, 1906, viii; ibid, 1906, viii, 240-243; *Zentralbl. f. Physiol.*, 1904, xviii, No. 16, *Jour. Physiol.*, 1904, xxxii, No. 1; ibid., 1905, xxxii, Nos 5 and 6; *Am. Jour. Physiol.*, 1902, vii, 243 259.

I also desire to call attention to the last volume of the Proceedings of the Society for Experimental Biology and Medicine, where will be found described a method for the determination of the viscosity, which has many points in common with Dr. McCaskey's, in spite of the fact that the said method has gained priority by publication.

I submit that the above references will show that the largest number of Dr. McCaskey's "conclusions" have been, to say the least, anticipated by others.

R. Burton-Opitz.

A proof of the above letter was submitted to Dr. McCaskey, who replies as follows:

Fort Wayne, Ind, Nov. 30, 1908.

To the Editor:—After re-examining my article on the viscosity of the blood, since reading the letter of Prof. Burton-Opitz, kindly submitted by you, I hasten to say that I have not given due credit to the work of that able investigator. It is scarcely fair on his part, however, to say that I do *not* refer to the early work of Hurthle, the fundamental character of which is distinctly mentioned on pages 1563 and 1564. The intimation that I am not familiar with the literature is also unjust. The abstracts alone which furnish a part of the literary basis of my paper occupy nearly fifty type written pages, legal cap size, and comprise nearly the entire literature of the subject. There was appended to these abstracts a bibliography which was as complete up to about April, 1908, as a capable abstractor, himself a physician, could make it from the material accessible in the surgeon general's office at Washington. It was manifestly impossible to utilize in my article more than a small part of this mass of material. The article was prepared by a clinician for clinicians, and I simply selected without much reference to the personality of the investigators such facts as would enable me to best present the subject for the purpose intended. I have very full abstracts of several of Professor Burton-Opitz's papers, more than one fact which he helped to establish being woven into the discussion without the acknowledgment which could properly have been given, and which should not have been entirely omitted. This was simply an unfortunate oversight, for which I am glad to have the opportunity to make amends, but which in no way affects the importance of the facts or the validity of the conclusions. There are other investigators who probably should have received more specific notice, although I particularly regret the present instance. In canvassing the literature alleged facts were carefully collated, and brought in touch with my own experience and observation, with the intention, of course, so far as practical in a brief paper, of crediting them to their source.

After all, however, the real questions of actual criticism, of this or any other paper, which most deeply concern the profession are the reliability of the facts, and the soundness of the conclusions set forth by the writer as fairly representing the present status of the subject. Individual facts, when poured into the common treasury, become common property and investigators must not expect clinical workers to label each fact with its paternity. This would burden clinical literature to an impossible degree.

Professor Burton-Opitz says that he has not used "*American Medicine* as a medium for publication." I did not say that he did. I only cited the location of the reference. With regard to one of the references to *American Medicine*, namely, the one to volume vii, page 111 (the other one is not at this moment accessible), the following are the facts: It is in the form of a special article reporting the Proceedings of the Society for Experimental Biology and Medicine. The article was furnished by William J. Gies, the secretary of the society, who says that the abstracts which he furnished were written by the authors themselves. If there is any issue here, I think it lies between Professor Burton-Opitz and the secretary of the Society for Experimental Biology and Medicine, and I will leave it to the readers of The Journal to decide whether such a bibliographic reference is or is not entirely proper, and also to form their own judgment of this sort of criticism.

His statement that the "largest number of my 'conclusions' have been, to say the least, anticipated by others" does not disturb me in the least. Among other things, it indicates that they are well founded. They might just as well have been labeled a summary, as they are nearly all of them based on the data contained in the article to which they are attached, and certainly, so far as I can see, do not contain even a suggestion of the absurd claim that they are based on individual research or investigation. They simply state in brief epitome what is my own judgment of the entire subject, based on a decidedly extensive and very nearly exhaustive review of the literature, and on clinical observation.

In "conclusion," I venture to express the hope that Professor Burton-Optiz, along with other original investigators, will continue to broaden and deepen our knowledge of scientific facts. For my part I will continue to plod modestly along the thorny clinical road on which every gleam of light from experimental science is more than welcome, and will be utilized to the fullest extent in solving the problems of practical medicine.

G. W. McCaskey.

Dr. John H. Rauch—A Pioneer in the Fight Against Quackery.

Galesburg, Ill., Dec. 5, 1908.

To the Editor:—To one who knew the late Dr. John H. Rauch, it is gratifying to read the appreciative letter of Dr. George Homan of St. Louis, in The Journal, December 5, regarding the work of Dr. Rauch while secretary of the Illinois State Board of Health. The committee on necrology of the Illinois State Medical Society for 1894 reports that Dr. John H. Rauch died at his birthplace, Lebanon, Pa., March 24, 1894. Whether or not he was buried there is not stated.

Dr. Rauch was the unconscious product of the demand for greater things in medicine. With clear vision he saw that the great thing, as well as the first thing, was the preliminary education of the individual seeking to practice medicine in Illinois. I well remember that when I entered this state from Minnesota to practice my profession, I was considerably worried to be told that I could not obtain a permit to practice until I was examined, not only from a literary, but from the medical point of view. After passing the literary examination before the late Newton Bateman, then president of Knox College, and also a member of the State Board of Health, I was able to secure a permit to practice by presenting proofs that I had taken a four-year course in one medical school before graduation. Before this time, I had never heard of such a procedure as a requisite to practice medicine in any state.

This personal experience was not coincident with the beginning of Dr. Rauch's greatest work, the promotion of higher medical education; but it was evidence of the work which he had already well started on the way, at least ten years before. It is said that when the Medical Practice Act of 1877 went into effect in Illinois, "about 3,600 non-graduates were practicing medicine in the state," and of these about 1,400 left the state or quit practice within a year of the passage of the law. It was said of Dr. Rauch at that time: "To him more than to any one else, indeed, more than to all others, are due the medical practice acts of other states, weeding out quackery, and the extended terms of medical colleges from three to four years, requiring additional study preliminary to conferring the medical degree." (Quoted from the *Sanitarian.*)

The promotion of higher medical education was but a small part of Dr. Rauch's activities. He was by instinct and training a scientist. He began this training as a private pupil of Prof. Louis Agassiz of Harvard College, and lived for some time in his family. It would be a pleasure to me, did space permit, to repeat here what the earlier chroniclers of this man's strong and efficient life had to say of him. These things influenced me and made me to know, as it did every other man and woman practicing the healing art in this state, that there was some one at the head of our State Board of Health who was potent. We felt the intensity of his strength. We knew that he had force and vigor and power, as well as the energy of achievement.

Dr. Rauch had faults; those of us who knew him can relate them. But back of some of his worst faults could be seen the cunning of the diplomat, whose consuming desire was the real advancement of his cause. Dr. Rauch was greater than his faults. He created. He had a mind and a brain, and above all a spirit that is still working among us.

He taught legislators how to bend the altruism of the medical profession to the public good. His professional life had in it the same essence that will make the names of Tyndall, Pasteur, Virchow, Koch and Lister immortal. It is no disparagement of those who have taken up his work since he left it in their care, that none has come who did more than work along the lines that he laid out. Dr. Rauch was a scientific sanitarian. In addition, he was a politician. How much of this latter training is now needed in our health boards is a question; but one thing is certain, the day has gone by when the state can afford to get along without a trained sanitarian as a part of its official health family.

All of which goes to show that, as pointed out by Dr. Homan, Illinois has not yet, in recognition of Dr. Rauch, her adopted son, done the *amende honorable*. At the present time, when the profession and the public have been taught the value of the work which he initiated, it would seem to be an opportune time to take up the question, as has been suggested, of putting in some permanent form the record of his great achievements. Just what form this memorial should take can well be left to the Illinois State Medical Society, of which he was an honorable and conspicuous member.

J. F. Percy.

Lacteal Secretion in the Male.

Chicago, Nov. 30, 1908.

To the Editor:—The remarks of Dr. Gellhorn, in his excellent article in The Journal, November 28, on "Abnormal Mammary Secretion," etc., *in re* the rarity of lacteal secretion in the male, recalls to my mind a case that may be of interest: A youth, 17 years of age, serving sentence for highway robbery, came under my care during my term of service at the Penitentiary Hospital, Blackwell's Island, N. Y. He was suffering from some minor pulmonary trouble—bronchitis, as I remember it. He objected to being stripped for examination. When this was done, it was found that his sensitiveness was due to his humiliation over the possession of two well-developed mammæ, of about the size of the average virginal breast at puberty. From these breasts I freely expressed lacteal secretion in moderate quantity and of a quality which, as shown by chemical and microscopic examination, was fully equal to the average standard of female lacteal secretion. According to the history, the condition had existed for about a year. The cause was unknown and the subject otherwise normal, the sexual apparatus being well developed.

As is true of most such institutional cases, the subject was lost sight of after he had served his term of punishment. Interne like, I regarded the case as a curio and did not recognize its scientific value, hence did not at that time report it. I have a hazy notion that I afterward did so, but if so, the journal in which it was reported is beyond my recollection.

G. Frank Lydston.

Sea-Water in Tuberculosis and Other Diseases.

Valdez, Alaska, Nov. 20, 1908.

To the Editor:—For the past two years I have been experimenting with sea-water as a remedial agent in tuberculosis, anemia, chlorosis and dyspepsia, and the result has been so gratifying that I feel constrained to publish the facts. I have had over twelve cases of pulmonary tuberculosis; four of the patients were bed-ridden. One patient gained 35 pounds in three months, another 16 pounds in one month, and after the first quart of sea-water ceased to have night sweats. Another patient gained 12 pounds in six weeks. All these patients have retained their weight, are apparently well, and have normal temperature. I have had the same experience in cases of anemia, chlorosis and some forms of dyspepsia, and I urge that a thorough test be made of sea-water in these diseases. My method is to have the patients drink from 1 to 3 pints of sea-water each day, and I have found that after taking it a day or two, the patients not only do not object to it, but seem to like it. Dr. Charles, in the *British Medical Journal*, reports some very interesting experiments with sea-water. He advocates diluting it with natural potable water, in the proportion of two parts to five; but I have found that there is very little objection to drinking it in its natural state. It is impossible, in the cities remote from the sea, to obtain the fresh sea-water, and I have had some carbonated, which renders it more palatable and equally efficacious.

E. C. Dalton.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

JOURNALS ON OPHTHALMOLOGY, OTOLOGY AND LARYNGOLOGY.

To the Editor:—Please give the names of the best and leading journals on ophthalmology, otology and laryngology.

J. M. Garber.

Answer.—The following are representative journals:

Annals of Otology, Rhinology and Laryngology, Mermod-Jaccard Bldg., St. Louis, $4 a year.

Annals of Ophthalmology, Mermod-Jaccard Bldg., St. Louis, $4 a year; with *Annals of Otology, Rhinology and Laryngology*, $7 a year.

Laryngoscope, 3858 Westminster Pl., St. Louis, $3 a year.

Ophthalmic Record, 72 Madison St., Chicago, $4.50 a year.

Journal of Ophthalmology and Oto-Laryngology, 100 State St., Chicago, $2 a year.

Ophthalmology, 105 Grand Ave., Milwaukee, $5 a year.

Journal of Laryngology, Rhinology and Otology, 21 St. Thomas St., London, S.E., England, $5 a year, including postage.

Archives of Ophthalmology, (Am. ed.), New Rochelle, N. Y., bi-monthly, $4.50 a year.

Archives of Otology (Am. ed.), New Rochelle, N. Y., bi-monthly, $4.50 a year.

The two last named are the American editions of the German journals of the same name.

HYDRARGYRUM SUCCINIDUM.

Eagle Grove, Iowa, Dec. 2, 1908.

To the Editor:—In the article on "Treatment of Tuberculosis by Mercury" in The Journal, Nov. 28, 1908, I come on this chemical product in closing the article. I do not ask, what is this, because I presume it may be possible to be amber mercury in such a way as to make it either a succinimid or a succinamid, an ammonia derivative of succinic acid. But is this salt official? This preparation is not mentioned in the U. S. Pharmacopeia, the Dispensatory, the National Formulary or New and Nonofficial Remedies. Why then should this rare chemical salt be the one selected in the very long list of mercurials available? That tuberculosis and syphilis exhibit striking pathologic similarities and probably yield to the same treatment is a plausible theory, but why the succinimid should be used in preference to other more familiar mercurial salts seem strange. This salt is certainly not only not to be found in text-books, but I doubt if one pharmacist in a thousand carries it or has ever heard of it. Why should one firm or institute have a corner on something that ought to be available and purchasable anywhere? In what does this differ from the commercial spirit that sells acetanilid under the names of antikamnia and antifebrin, or that tries to monopolize the tuberculosis market with Lloyd's Aicsol or Robert's Hydrocine or reduce the corpulent with thyroid extract under title of marmola, rengo and other strange names? If the succinimid of mercury cures tuberculosis, does not the protoiodid, the biniodid, the mild or the strong chlorid or even the old fashioned unguentum hydrargyri? But if the succinimid, on the contrary, is the only salt of mercury that cures tuberculosis, then by all means let us get it on the official list at the next revision of the U. S. P.

H. K. Henriksen, M.D.

Answer.—Mercury succinimid is a definite chemical substance. It is the mercury salt of the imid of succinic acid. The Council on Pharmacy and Chemistry has accepted mercury succinimid as a non-proprietary substance for inclusion with the next edition of New and Nonofficial Remedies, which will appear about January 1. There has been little if any call for the drug in the American market, consequently it may not be kept in stock by distributors or pharmacists.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Dec. 5, 1908:

Kennedy, J. M., major, ordered to report Dec. 1, 1908, for duty as acting chief surgeon, Department of California.

Merse, C. F., capt., relieved from duty at Fort Howard, Md., and directed to proceed to Fort Huachuca, Ariz., to accompany troops to the Island of Oahu, H. T., for duty there.

Williams, A. W., capt., granted leave of absence for 3 months.

O'Reilly, R. M., brig.-general; Russell, Frederick F., capt., and Vaughan, V. C., Councilman, W. T., Musser, J. H., Lambert Alex., Flexner, Simon, Thayer, W. S., 1st lieuts., M. R. C., appointed a board to meet at Washington, Dec. 7, 1908, to investigate the question of immunizing the Regular, and, in case of war, the Volunteer Army against typhoid fever.

Trotter-Tyler, G., M. R. C., ordered from Fort Adams, R. I., to Fort Revere, Mass., for temporary duty.

Stephenson, A. V., M. R. C., honorably discharged from the service of the U. S.

Enders, W. J., M. R. C., granted leave of absence for 10 days.

Kelly, J. P., M. R. C., relieved from duty at Fort Miley, Cal., and ordered to duty at the camp to be established on the Island of Oahu, H. T.

Vaughan, V. C., Councilman, W. T., Musser, J. H., Lambert, Alex., Flexner, Simon, Thayer, W. S., M. R. C., ordered to active duty in the service of the U. S.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Dec. 5, 1908:

Curtis, E. E., asst.-surgeon, ordered to the *Chattanooga*.

Olson, G. M., asst.-surgeon, ordered to the *Culgoa*.

Stokes, C. F., surgeon, detached from command of the *Relief* and ordered home.

Spear, R., surgeon, detached from the *Relief* and ordered to the *Rhode Island*.

Dessez, P. T., P. A. surgeon, detached from duty at the naval hospital, Mare Island, Cal., December 31, and ordered to the Pacific Fleet, sailing from San Francisco, about January 5.

Dunbar, A. W., surgeon, ordered to command the *Relief*.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service for the seven days ended Dec. 2, 1908:

Cobb, J. O., surgeon, granted 15 days' leave of absence from Dec. 22, 1908.

Stoner, J. B., surgeon, directed to proceed to Louisville, Ky., Cairo, Ill., and Memphis, Tenn., on special temporary duty, Nov. 17, 1908.

Cofer, L. E., P. A. surgeon, directed to report to Director Hygienic Laboratory for temporary duty, Nov. 27, 1908.

Cofer, L. E., P. A. surgeon, granted 4 days' leave of absence from Dec. 1, 1908, under Paragraph 191, Service Regulations.

Billings, W. C., P. A. surgeon, bureau orders of Nov. 3, 1908, detailing him for duty on the Revenue Cutter *Itasca*, amended, detailing him for duty at the Revenue Cutter School of Instruction, Arundel Cove, Md., Nov. 26, 1908.

Corput, G. M., P. A. surgeon, granted 10 days' leave of absence from Dec. 8, 1908.

Foster, Albert D., P. A. surgeon, relieved from duty on the Revenue Cutter *Thetis;* directed to proceed to Angel Island, Cal., and report to commanding officer, Nov. 26, 1908.

Lanza, A. J., asst.-surgeon, relieved from duty on the Revenue Cutter *Rush;* directed to report to commanding officer of the Revenue Cutter *McCulloch*, for duty.

Oleson, Robert, asst.-surgeon, on being relieved by Assistant Surgeon A. J. Lanza, directed to proceed to Marine-Hospital, San Francisco, and report to commanding officer for temporary duty.

Duke, B. F., acting asst.-surgeon, granted 23 days' leave of absence from Nov. 23, 1908.

Gustetter, A. L., acting asst.-surgeon, granted 6 days' extension of leave of absence from Nov. 26, 1908.

Thompson, W. R. P., acting asst.-surgeon, leave of absence for 30 days from Nov. 23, 1908, granted Nov. 11, 1908, revoked Nov. 27, 1908.

BOARD CONVENED.

Board of medical officers convened to meet at the Marine-Hospital, Baltimore, Dec. 2, 1908, for the re-examination of a cadet of the U. S. Revenue Cutter Service. Detail for the board: Surgeon W. P. McIntosh, chairman; P. A. Surgeon J. W. Schereschewsky, recorder.

CASUALTY.

Miller, W. W., asst.-surgeon, died in Washington, D. C., Nov. 24, 1908.

Health Reports.

The following cases of small pox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service during the week ended Dec. 4, 1908:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 7-14, 8 cases.
Kansas: Topeka, Nov. 7-14, 7 cases.
Ohio: Cincinnati, Nov. 13-20, 2 cases.
Tennessee: Nashville, Nov. 14-21, 1 case.
Texas: Encinal, Oct. 22-Nov. 26, 49 cases.
Washington: Spokane, Oct. 7-14, 1 case; Tacoma, Oct. 24-Nov. 1, 4 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Oct. 3-10, 4 cases.
Algeria: Algiers, Oct. 1-31, 22 deaths.
Arabia: Aden, Oct. 19-Nov. 2, 19 deaths.
Brazil: Bahia, Sept. 1-30, 174 cases, 6 deaths.
Canada: Halifax, Nov. 7-14, 4 cases; Victoria, 1 case.
Ceylon: Colombo, Oct. 3-17, 56 cases, 11 deaths.
Egypt: Cairo, Oct. 21-28, 7 cases, 1 death.
France: Paris, Oct. 24-Nov. 7, 4 cases.
India: Bombay, Oct. 20-27, 2 deaths; Calcutta, Sept. 26-Oct. 10, 3 deaths.
Italy: General, Nov. 1-8, 4 cases; Naples, 12 cases.
Russia: Odessa, Sept. 26-Oct. 3, 2 cases; Warsaw, Oct. 10-17, 5 deaths.
Spain: Barcelona, Oct. 31-Nov. 7, 2 deaths.
Turkey: Constantinople, Nov. 1-8, 7 deaths.

YELLOW FEVER.

Brazil: Bahia, Sept. 1-30, 1 death; Para, Oct. 17-24, 3 cases, 3 deaths.
Martinique: Port de France, Oct. 24-31, 1 case.
Mexico: Campeche, Nov. 7-14, 1 case; Merida, 5 cases, 3 deaths; Vera Cruz, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Oct. 3-10, 55 cases, 14 deaths; Provinces, 1,276 cases, 738 deaths.

CHOLERA—FOREIGN.

China: Hankau, Oct. 27, present.
India: Bombay, Oct. 20-27, 1 death; Calcutta, Sept. 26-Oct. 10, 20 deaths; Madras, Oct. 17-23, 7 deaths.
Russia: General, to Oct. 24, 25,509 cases, 11,962 deaths; St. Petersburg, Sept. 26-Oct. 24, 7,574 cases, 3,121 deaths.
Straits Settlements: Singapore, Oct. 10-17, 1 case.
Japan: Moji, to Oct. 28, 2 cases; Obama, 1 case; Sasebo, to Oct. 2, 2 cases; Tsushima, 7 cases.

PLAGUE.

Brazil: Bahia, Sept. 1-30, 8 deaths; Para, Oct. 10-17, 1 case, 1 death.
Chile: Iquique, Oct. 23-26, 3 cases; present.
India: General, Oct. 10-17, 3,717 cases, 2,649 deaths; Bombay, Oct. 20-27, 12 deaths; Calcutta, Sept. 26-Oct. 10, 13 deaths; Rangoon, Oct. 10-17, 6 deaths.
Peru: General, Oct. 15-28, 38 cases, 25 deaths; Lima, 7 cases, 1 death.

Association News

NEW MEMBERS.

List of new members of the American Medical Association for the month of November, 1908:

ALABAMA.

Mason, E. M., Montgomery.
Street, T. H., Alexander City.

ARKANSAS.

Murchison, A. J., England.
Sheriff, J. P., Supply.

CALIFORNIA.

Houston, Albert, San Francisco.
Holt, Wm. L., Santa Barbara.
Hurst, J. H., Montecito.
Irwin, W. H., Oakland.
Kiuell, F. J., Los Angeles.
Lewis, Will J., Santa Yuez.
Olmsted, R. C., Pasadena.

COLORADO.

Emery, E. W., Denver.
Hill, C. A., Trinidad.
Klinkowstroem, E. V., Denver.
Perkins, J. M., Denver.

CONNECTICUT.

Chedel, C. B., Kensington.

DELAWARE.

Dwight, E. S., Smyrna.

IDAHO.

Judd, H. H., Wallace.

ILLINOIS.

Beck, H. E., Moline.
Coquillette, W. E., Byron.
Ecke, A. C., Chicago.
Frantz, D. W., Metcalf.
Hoffmann, F. F., Chicago.
Miller, Ira M., Chicago.
Koessler, K. K., Chicago.
Pagano, Raffaele, Chicago.
Pease, L. W., Chicago.
Pfeifer, J. P., Chicago.
Wrightsman, Edward C., Chicago.

INDIANA.

Burroughs, J. P., Westport.
DuBois, C. C., Warsaw.
Dutton, H. H., Paragon.
Fair, H. D., Muncie.
Hall, Silas, Vincennes.
Harrod, N. G., Tampico.
Lockwood, R. L., Elkhart.
Mathews, W. R., Madison.
Magers, F. M., Churubusco.
Morr, J. W., Albion.
Nixon, John, Farmland.
Norris, A. A., Elkhart.
Osbon, G. G., Jasonville.
Parker, J. J., Merom.
Shoemaker, G. L., North Manchester.
Stamets, Z. H., Auburn.
Stephenson, T. J., Lapel.
Sweet, E. M., Martinsville.
Wells, M. M., Fairland.
Yarling, J. E., Peru.

IOWA.

Clarke, F. S., Lemars.

KANSAS.

Lidikay, C. J., Kansas City.
Vallette, H. B., Jewell.

KENTUCKY.

Ford, E. W., Hartford.
Helm, T. O., Auburn.
Marks, S. B., Lexington.
Quaife, C. E., Louisville.
Wright, C. A., Cayce.

MARYLAND.

Brülle, Herman, Baltimore.
Hebb, A., Baltimore.
Naylor, H. A., Pikesville.

MASSACHUSETTS.

Galvin, A. H., Salem.
Hatch, Royal, Wellesley.
Oliver, E. L., Boston.

MICHIGAN.

Anderson, J. W., Royal Oak.
Baker, Norman L., Milford.
Belanger, J. A., Grosse Pointe.
Clemes, W. T., Blissfield.
Doran, W. E., Colon.
Ferguson, J. A., Rudyard.
Francis, A. M., Port Austin.
Frankhauser, Silas, Hillsdale.
Greenmyer, J. D., Niles.
Hanna, W. B., Mass.
Husband, F. H., Sault Ste. Marie.
Jones, A. J., Painesdale.
McBurney, W. W., Stambaugh.
McVicar, N. D., Lum.
Newcomb, S. O., Ida.
Nitterauer, J. S., Ontonagon.
Nottingham, Bert, Lansing.
Osborne, D. P., Kalamazoo.
Quick, J. B., Kearsage.
Rhines, James, Jr., Mohawk.
Simenton, George, Marlette.
Sleneau, Talbert, Port Huron.

MINNESOTA.

Beachler, G. F., Minneapolis.
Franzen, H. G., Minneapolis.
Guilford, H. M., Minneapolis.
Haynes, F. E., Minneapolis.
Laudenberger, John, New Prague.
Monahan, J. A., Minneapolis.
Phillips, W. H., Jordan.
Pratt, F. J., Jr., Minneapolis.
Silvertsen, Ivar, Minneapolis.
Wilcox, M. R., Minneapolis.
Williams, C. W., Minneapolis.

MISSOURI.

Campbell, O. H., St. Louis.
Chalkley, A. J., Lexington.
Cope, J. O., Lexington.
Laurenzana, D. A., Kansas City.
Lewis, E. A., Rock Port.
Owens, J. H., Sweet Springs.
Wilson, Roy E., LaBelle.

MONTANA.

Cuttle, Frederick, Hunters Hot Springs.

NEBRASKA.

Barnes, E. M., Plainview.
Conklin, R. E., Alma.
Martyn, D. T., Columbus.
Smith, H. C., Franklin.

NEW JERSEY.

DuBois, F. E., Plainfield.

NEW MEXICO.

Parr, H. F., Carlsbad.

NEW YORK.

Amster, J. L., New York City.
Bailey, H. C., New York City.
Bickford, J. W., Lockport.
Biggar, H. R., Glen.
Chase, G. T., New York City.
Cleland, F. A., New York City.
Fischlowitz, G. G., New York City.
Foster, M. L., New York City.
Gordon, C. A., Brooklyn.
Gregory, Alice, New York City.
Hengerer, Louis, Hamburg.
Jackson, G. B., Angelica.
Knight, C. C., Peekskill.
Langmann, G. A., New York City.
Lathrope, G. H., Binghamton.
Lawrence, R. A., Albany.
MacKenzie, D. A., New York City.
Merwin, E. B., Manlius.
Norris, H. S., New York City.
Patterson, C. J., New York City.
Remer, John, New York City.
Scofield, C. E., Brooklyn.
Squire, A. P., Rotterdam Junc.
Stone, Thomas, New York City.
Thomas, L. A., Painted Post.
Titus, H. W., New Rochelle.
White, H. D., Rome.
Whitbeck, S. V., Hudson.
Wilcox, D. G., Buffalo.
Wiseman, J. R., Syracuse.

NORTH CAROLINA.

Howe, W. B. W., Hendersonville.

OHIO.

Baird, R. J., Creston.
Buel, J. J., Cleveland.
Clingaw, T. O., Niles.
Gardner, G. R., Ashville.
Haris, E. C., Springfield.
Hitchcock, S. A., Lima.
Landor, T. H., Canton.
Lang, M. W., Ridgeville.
Lietze, Bertha C., Cincinnati.
McClenahan, C. W., Collingwood

Miller, Louis, Toledo.
Millette, J. W., Dayton.
Murphy, J. J., Lima.
Norton, F. B., Cleveland.
Speer, A. T., Newark.
Tenney, C. F., Toledo.
Ward, C. S., Warren.

OKLAHOMA.

Baker, R. L., Wynnewood.
Huddle, W. T., Lamont.
Powell, J. P., Olney.
Reed, O. D., Frederick.
Ruhl, N. E., Piedmont.
Shippey, R. H., Chickasha.
Troutt, L. W., Afton.
Vick, J. T., Fort Towson.

PENNSYLVANIA.

Gilliland, J. F., Beaver Falls.
Ridgway, R. F. L., Harrisburg.
Rentschler, H. F., Reading.

TEXAS.

Clutter, B. F., El Paso.
Hickey, M. L., Chalk Mountain.
Johnson, I. F., Gatesville.
Martin, R. G., La Verina.
Ponton, A. R., Copperas Cove.
Winn, Wm. A., Tuscola.

VERMONT.

Leonard, L. L., Barre.

VIRGINIA.

Richardson, A. S., Hurley.
Woolwine, W. D., Pearlsburg.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

The Danger of Signing Petitions.

Under the above title, the *New York State Journal of Medicine* for November comments editorially on a frequently noted failing of members of our profession, namely, that of signing petitions and endorsing movements of all sorts without giving careful consideration to the merits of the plan or individuals endorsed. The editorial calls attention to the coming meeting of the state legislature and to the large number of bills which will probably be introduced, many of which will affect the profession or the public from the standpoint of the physician. Regarding this mass of proposed legislation the editorial says, "Some of these measures are worthy and should become laws. Others are either poorly digested or crude efforts to cure real or imaginary ills by legislation. Some are purely local in character and while they might help a particular individual or locality, if applied to the entire state would be uncalled for or even harmful. Some of the proposed measures conflict with laws already in existence and would cause much confusion if passed. Many are clearly unconstitutional, while others are unnecessary or vicious."

Attention is then called to the machinery which has been devised for county and state societies with a view to considering and handling legislative matters. Each county society has or should have a committee on legislation, while the committee on legislation of the state society has general oversight and charge of all legislative matters. These committees "employ many means to present arguments to the legislator for or against proposed legislation, among them being the signing and forwarding to the legislature of properly worded petitions. This method is also employed by those who desire to promote public sentiment for or against proposed legislative methods and very frequently medical men are asked to sign such petitions. A request to sign may be made by a friend and for that reason the signature may be given without any really careful thought being accorded the proposed measure, or the petition may be presented by a plausible and tactful agent who may explain all the benefits and omit all the disadvantages of the bill if it should become a law." Members of the state society are urged to refrain from signing petitions or endorsing legislation which they do not thoroughly understand, and which has not already been approved by the regularly constituted committees. "Unless great care is exercised many will find to their sorrow that their approval has been secured for measures which, when they have time to study them carefully, meet with their hearty disapproval or condemnation. . . . How much wiser it would be for the doctor, when asked to approve or disapprove of impending or proposed legislation, to refuse to sign such petitions and to await the action of the state society of which he is a member, and through which he can speak by action of his house of delegates or committee on medical legislation?"

This editorial admirably emphasizes a shortcoming of our profession which must be corrected if medical organizations are ever to perform properly their duties to their members and to society. Physicians as a class must learn to work in regular systematic channels and through existing constituted means. There is nothing to be gained by electing officers and appointing committees for specific purposes, if the individual member is to ignore such officials and approve or disapprove important measures on his individual responsibility and opinion. Such a method can mean only a relapse into the disorganized, individualistic state of conflicting personal opinions, multitudinous views and lack of practical results from which we are just emerging. Nor are practical illustrations of the dangers of such a course wanting. During a recent session of a state legislature, the committee on public policy of the state association was vigorously opposing the passage of a certain bill on the ground that the entire state association which it represented was opposed to its passage. Much to the embarrassment of the committee, it was learned that one of the sections of the state society had, without any adequate consideration adopted a resolution endorsing the same measure which the committee on legislation was opposing.

Such incidents are by no means creditable, although perhaps instructive. Individual members as well as county societies—unless they thoroughly understand the subject and have good reasons for doing otherwise—should refrain from approving or disapproving proposed legislation, leaving this task to the properly constituted committees which have carefully considered the subject. The work of the individual member and society should be limited to carrying out the recommendations of the committee on legislation. Such a plan is not "machine rule," depriving the individual member of his right of opinion, etc., but is merely the subordination of the individual to the organized body for the general good, and is the substitution of an intelligent, carefully considered decision for a hasty and often erroneously conceived opinion of the measure in question.

Medical Service Bills Endorsed.

The Marin County (Calif.) Medical Society has adopted resolutions endorsing the United States Public Health and Marine-Hospital Personnel Bill, providing pay for the officers of the service on an equality with that received by officers of the Army and Navy. Resolutions have been adopted by the Northeastern Dental Association, a body composed of dentists from Maine, New Hampshire, Massachusetts, Rhode Island and Connecticut, endorsing the bills providing for a dental corps in the Army and Navy, as proposed by the surgeon-generals of the army and war departments.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR. JOHN H. BLACKBURN, DIRECTOR.
Bowling Green, Kentucky.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Fifth Month—First Weekly Meeting.

General Subject for the Month: Non-Venereal Diseases of the Genitourinary Tract.

ANATOMY OF BLADDER AND URETHRA.

Bladder.—Location, surface markings, shape, size, relations, space of Retzius. Surfaces, sides, apex. Base, neck of bladder, intervesicular triangle, vesicle trigone. Ligaments, blood vessels, nerves, lymphatics. Structure of bladder wall.

Urethra.—Shape and variations, length, curves, caliber, divisions. (a) Prostatic, length, shape, boundaries, verumontanum, prostatic sinus, orifices of prostatic ducts, of ejaculatory ducts. (b) Membranous, length, shape, boundaries. (c) Spongy or penile, length, boundaries, shape, fossa navicularis, bulbous portion, meatus, glands of Littré, ducts of Cowper's glands. Structure of urethra, mucous coat, submucous coat.

ANATOMY OF PROSTATE GLAND AND PENIS.

Prostate.—Location, shape, size, relations, prostatic muscle, prostatic fascia, true capsule, apex, base, surfaces, lobes. Structure, muscular and glandular tissue. Vessels, nerves and lymphatics.

Cowper's Glands.—Location, size, structure.

Penis.—Root, crura, suspensory ligament. Body, shape, size, integument, surfaces. Extremity, meatus, glans, corona, cervix, glandulæ. Structure: (a) corpora cavernosa, fibrous sheath (tunica albuginea), crus, bulb, septum, trabeculæ, cavernous spaces, distribution of arteries, veins; (b) corpus spongiosum, relations, bulb of urethra, body, glans penis, fibrous layer, trabeculæ. Vessels, nerves and lymphatics of penis.

ANATOMY OF SCROTUM AND TESTICLE.

Scrotum.—Skin, structure. Dartos, structure, attachments, septum scroti. Intercolumnar fascia. Cremasteric fascia and muscle. Infundibuliform fascia. Spermatic cord, relations, coverings, arteries, veins, spermatic duct, lymphatics.

Testicle.—Size, shape, position. Testis, extremities, borders and surfaces. Epididymis, globus major, body, globus minor. Tunica vaginalis, origin, visceral and parietal layers. Tunica albuginea, structure, relations, trabeculæ. Tunica vasculosa. Structure, lobules, convoluted and straight tubes, efferent ducts. Spermatozoids. Epididymis. Seminal duct. Semen. Seminal vesicles, size, shape, location, structure. Ejaculatory ducts.

REFERENCE BOOKS FOR THE FIFTH MONTH.

White and Martin: Genitourinary and Venereal Diseases.
Casper: Text-book of Genitourinary Diseases.
Keyes: Genitourinary Diseases.
Taylor: Genitourinary and Venereal Diseases.
Green and Brooks: Diseases of Genitourinary Organs and Kidneys.

Marriages

W. Louard Cash, M.D., to Miss Ida Effa Nichols, both of Princeton, Ky., November 19.

Otto C. Gaebe, M.D., Addieville, Ill., to Miss Alma B. Wilde of New Athens, Ill., December 2.

Wilson T. Davidson, M.D., U. S. Army, to Miss Mary Hudson, at Bolton, Texas, November 23.

Henry Clay Cowles, M.D., to Miss Grace Truman Fuller, both of New York City, November 24.

Charles M. Kennedy, M.D., Camden, Ind., to Eva Nebeker, M.D., of Covington, Ind., November 25.

Thomas S. Egan, M.D., Mapleton, Ill., to Miss Winifred M. Leonard, of Newark, N. J., November 25.

James Fulton Burnam, M.D., Huntsville, Ala., to Miss Laura Dillard, of Triana, Ala., November 24.

Charles W. Eisenhower, M.D., Jacobus, Pa., to Miss Sadie A. Boyer, of York, Pa., November 24.

Japheth Edward Rawls, M.D., to Miss Emma Copeland Holland, both of Suffolk, Va., November 24.

A. R. Sweeney, M.D., Lake Arthur, La., to Miss Rilla D. Ingram, of Wichita Falls, Texas, December 1.

J. Everett Pickering, M.D., to Miss Mildred Frances Bliss, both of Coldbrook Springs, Mass., November 29.

Lester Brooks Rogers, M.D., to Miss Louise Tarbell, both of New York City, at Garden City, N. Y., recently.

Paul Randolph Stalnaker, M.D., U. S. Navy, to Miss Florence Dana West of Austin, Texas, November 10.

J. W. S. Cross, M.D., Telluride, Colo., to Miss Ethelwyn A. Davenporte, of Picton, Ont., in Denver, November 19.

Patrick F. Griffin, M.D., Honesdale, Pa., to Miss Jennie Renn, of Bloomsburg, Pa., in New York City, November 25.

Deaths

Andrew J. McCosh, M.D., one of the most prominent surgeons of the east; died in the Presbyterian Hospital, New York, December 2, from injuries received in a runaway accident four days before, aged 50. Dr. McCosh was a son of the late President James McCosh of Princeton University. He received his A.B. and A.M. degrees from Princeton University, was graduated from the College of Physicians and Surgeons, New York City in 1880, and was given the honorary degree of LL.D. by Columbia University in 1905, and by Princeton University in 1906. He took a course of postgraduate study in the University of Vienna in 1882, and in 1883 began practice in New York City. He served his alma mater as clinical lecturer in surgery and later as professor of clinical surgery. For the last nineteen years he was a member of the staff of the Presbyterian Hospital as visiting surgeon, attending surgeon, and surgeon-in-chief; he was also attending surgeon to Roosevelt Hospital. His society memberships included the American Medical Association, the American Surgical Association, International Surgical Society, and American Society of Clinical Surgery. At the recent meeting of the International Medical Congress he read an interesting and important paper on peritonitis. Dr. McCosh won distinction not as a specialist, but as a general surgeon. While going on a professional errand November 28, one of his horses became frightened at an automobile, the buggy was overturned, and Dr. McCosh was dragged in the wreckage. He was taken to Presbyterian Hospital, where it was found that he had suffered a fracture of the base of the skull, a compound fracture of the clavicle, and other injuries, which, together with a pneumonia that developed from the exposure, caused his death four days later.

Francis J. Ives, M.D. U. S. Army; University of Virginia, Charlottesville, 1878; a member of the American Medical Association and Association of Military Surgeons of the United States; who entered the medical corps of the Army in 1881; and twenty years later was promoted to major and surgeon; served as brigade surgeon during the Spanish-American War; won especial praise for the conduct of his field hospital at the battle of El Caney; served later in the Philippine Islands and in China; and later on was in charge of the general hospital in Manila and was retired on account of physical disability a few weeks ago; died at his home in Washington, D. C., November 27, from cirrhosis of the liver, arising from tropical service, aged 51.

William Wallace Woodring, M.D. Miami Medical College, Cincinnati, 1867; University Medical College of Kansas City, 1898; a member of the American Medical Association; formerly president of the Sanpete County (Utah) Medical Society; a member of the board of delegates of the Utah State Medical Association and of the National Council of Medical Legislation for Utah; a member of the U. S. Pension Examining Board; local surgeon of the Denver and Rio Grande Railway; and health officer of Mount Pleasant, Utah; a Confederate veteran; died at Holy Cross Hospital, Salt Lake City, November 22, from uremia, aged 67.

William Miller, M.D. University of Pennsylvania, Philadelphia, 1875; a member of the American Medical Association; for six years a member and for four years secretary of the State Board of Medical Examiners of Texas; health officer of Kendall County and city physician of Rockport, Texas; founder and physician-in-chief of St. Mary's Sanitarium, Boerne, Texas; died recently at his home in Ormond, Fla., from uremia, aged 52.

Luther G. McCollum, M.D. Maryland Medical College, Baltimore, 1904; a member of the Medical Association of the State of Alabama; and a prominent young practitioner of Birmingham; died at St. Vincent's Hospital in that city, November 24, from septicemia, aged 26. The Jefferson County Medical Society, at a special memorial meeting held the same day, passed resolutions regarding Dr. McCollum's death.

James Hall Heed, M.D. Tulane University, New Orleans, 1868; Jefferson Medical College, Philadelphia, 1870; for many years a member of the American Medical Association; a member of the Michigan State Medical Society; a Confederate veteran; died suddenly at his home in Battle Creek, Mich., November 25, from cirrhosis of the liver, aged 64.

Rush J. Shank, M.D. University of Michigan, Ann Arbor, 1871; a member of the Michigan State Medical Society; a veteran of the Civil War and department commander of the G. A. R. of Michigan in 1874 and 1875; a member of the common council of Lansing; died at his home in that city November 25, from peritonitis, aged 59.

William Elwin Rogers, M.D. Georgetown University, Washington, D. C., 1904; a member of the Medical Association of the District of Columbia and the District of Columbia Mental and [illegible] member of the staff of Providence [illegible] died in that institution, November 22, aged 30.

Ernest A. Matthaei, M.D. College of Physicians and Surgeons, Chicago, 1895; of Chicago; a member of the Illinois State Medical Society; associate in obstetrics at the Evangelical Deaconess Hospital, and assistant in surgery in the Chicago Polyclinic Hospital, died December 4, in Sierra Madre, Cal., aged 40.

Benjamin F. Dexter, M.D. College of Physicians and Surgeons, New York City, 1876; a veteran of the Civil War; and a police surgeon of New York City for more than twenty-five years; died at the home of his niece near Lockport, N. Y., November 16, from senile debility, aged 78.

George Edward Babbitt, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1876; of East Orange, N. J.; died at the Orange Memorial Hospital, November 23, from fracture of the base of the skull due to a kick by a horse in a runaway accident the day before, aged 49.

Gabriel Pellet Reeves, M.D. New York University, New York City, 1845; for a long time physician of Orange County, N. Y., and secretary and treasurer of the county medical society; died at his home in Yonkers, N. Y., from senile debility, November 25, aged 88.

Henry Frederick Angle, M.D. University of Pennsylvania, Philadelphia, 1869; formerly of Williamsport, Md.; sometime physician to the Washington County Almshouse; died, November 20, at his home in Brockton, Mass., from heart disease, aged 68.

Lucius Cary Allison, M.B., C.M. University of Edinburgh, Scotland, 1868; from 1873 to 1891 a member of the visiting staff of the General Public Hospital, St. John, N. B.; died at his home in St. John, November 26, from heart disease, aged 63.

Jeremiah Johnson, M.D. University of Maryland, Baltimore, 1852; for a number of years a resident of Waverly and physician of Wood County, W. Va.; died at the home of his daughter in Hagerstown, Md., November 30, from paralysis, aged 79.

Charles Williams Bailey, M.D. University of Maryland, Baltimore, 1889; a member of the American Medical Association; for 14 years in the U. S. P. H. and M.-H. Service; died at his home in Georgetown, S. C., November 24, aged 39.

Handley Nelson Bushnell, M.D. New York University, New York City, 1848; for many years a practitioner of Cape Vincent, N. Y.; died at the home of his daughter in East Orange, N. J., November 28, from senile debility, aged 81.

Reuben Camp Baldwin, M.D. Castleton (Vt.) Medical College, 1851; for nearly half a century a practitioner of Oswego, N. Y.; died at the home of his daughter in Syracuse, November 6, from senile debility, aged 84.

James Harvey Bates, M.D. Long Island College Hospital, Brooklyn, 1875; for many years a practitioner of Chicago; died in St. Luke's Hospital in that city, December 3, from postoperative pneumonia, aged 68.

De Witt Clinton Fowler, M.D. College of Physicians and Surgeons, New York City, 1863; died in his apartments in the Commercial Club, Aberdeen, S. D., November 25, from cerebral hemorrhage, aged 71.

Richard Thomas Gott, M.D. University of Maryland, Baltimore, 1868; subregistrar of the State Board of Health of Maryland; died at his home in Poolesville, November 26, from kidney disease, aged 64.

Henry Reder, M.D. New York University, New York City, 1880; formerly president of the Board of Health of Aurora, Ill.; died at his home in that city, from cirrhosis of the liver, November 23, aged 56.

Granger V. Randall, M.D. Chicago Homeopathic Medical College, 1883; a member of the Michigan State Medical Society; died suddenly at his home in Tecumseh, Mich., from pleurisy, November 25, aged 50.

Edward E. Collins, M.D. New York University, New York City, 1857; for forty years a practitioner of Minnesota; died in Unadilla Forks, N. Y., November 20, from intestinal obstruction, aged 75.

James M. Harris, M.D. Bellevue Hospital Medical College, New York City, 1868; of Yellow Springs, Ohio; formerly professor in Antioch College; died recently, in the Isle of Pines, Cuba, aged 70.

Chauncey B. Fowler, M.D. Long Island College Hospital, Brooklyn, 1878; a member of the Medical Society of the State of New York; died at his home in Brooklyn, October 30, aged 60.

Thomas Monroe Lanahan, M.D. Cleveland University of Medicine and Surgery, 1893; died at the home of his parents in Southington, Ohio, November 28, from heart disease, aged 39.

Harvey F. Craig, M.D. Baltimore University, 1888; of Griffithsville, W. Va.; died in the Charleston (W. Va.) General Hospital, November 24, from cerebral hemorrhage, aged 47.

Walter A. Bacon, M.D. Baltimore University, Maryland, 1898; of Pawtucket, R. I.; died at the home of his sister in Riverside, R. I., November 22, from nephritis, aged 35.

Vernon Amasa Dunshee, M.D. College of Physicians and Surgeons, Chicago, 1905; formerly of Palatka, Fla.; died in Asheville, N. C., November 19, from tuberculosis, aged 29.

Albert Burke, M.D. Baylor University, Dallas, Texas, 1903; a member of the American Medical Association; died at his home in San Antonio, Texas, November 21, aged 42.

William James Grimes, M.D. Jefferson Medical College, Philadelphia, 1881; a member of the Medical Society of Virginia; died at his home in Norfolk, November 28, aged 54.

Edward Anthony Mock, M.D. Bellevue Hospital Medical College, New York City, 1896; died at his home in Cambridge, Ill., November 21, from heart disease, aged 37.

T. A. Benbow (License, Colo., 1885); for more than thirty-three years a practitioner of Colorado; died at his home in Colorado Springs, November 18, aged 77.

Washington L. Hood, M.D. University of Georgia, Augusta, 1887; died suddenly at his office in Nicholson, Ga., November 18, from heart disease, aged 54.

Howard Finch Hawkins, M.D. College of Physicians and Surgeons, Baltimore, 1896; died at his home in Pine, Colo., Nov. 30, 1907, aged 34.

Joseph J. Judy, M.D. Eclectic Medical Institute, Cincinnati, 1866; died at his home in San Antonio, Texas, from paresis, September 1, aged 69.

Sylvanus F. Cosgrove, M.D. Cincinnati College of Medicine and Surgery, 1875; died at his home in Swanton, Ohio, November 23, aged 61.

A. San Martin, M.D. professor of surgery at the University of Madrid; former senator and cabinet minister; died November 9. He was at one time editor of the *Siglo Medico*, and always took a leading part in all matters affecting the welfare of the profession and the progress of science. The issue of the *Siglo Medico*, November 14, describes his career and last sickness with the autopsy findings—his will bequeathing his body to the dissecting table as his last contribution to science.

Sir Henry Pitman, M.D. Cambridge, 1841; F.R.C.P., London, 1845; registrar of the Royal College of Physicians, London, from 1858-1880; lecturer on "Principles and Practice of Medicine" and later consulting physician to St. George's Hospital, London; died at his home in Enfield, Middlesex, England, November 6, aged 100.

Society Proceedings

COMING MEETINGS.

Southern Surgical and Gynec. Assn., St. Louis, Dec. 15-17.
Western Surgical and Gynec. Assn., Minneapolis, Dec. 29 30.
American Assn. of Anatomists, Baltimore, Dec. 29-31.

SOUTHERN MEDICAL ASSOCIATION.

The Necessity of Pure Food and Drug Regulation and the Education of the People in the Prevention of Disease.

Second Annual Meeting, held at Atlanta, Ga., Nov. 10-12, 1908.

(Concluded from page 1995.)

Dr. D. Harvey Dillon, New Orleans: We should have uniform laws throughout the states regulating the sale of food and drug products, not only to protect the consumer, but in justice to the manufacturer and dealer. The laws in the various states are so different as to the labeling and branding of food and drug products that it costs the manufacturers of the United States large sums of money to comply with them. If the legislatures of the various states would give to their respective boards of health authority to write a sanitary code and a pure food and drug law, it would then be possible through the national association of health officers to formulate a uniform law.

Toxic Arthritis of the Hip Joint in Children; Diagnosis and Treatment.

Dr. Michael Hoke, Atlanta, Ga.: There is a non-tuberculous, non-articular hip inflammation occurring in children and young people in their teens and presenting all the symptoms and physical signs of tuberculosis of the hip joint. In the last eighteen months 45 patients with hip-joint disease (children and young people), presenting the classical signs and symptoms of tuberculosis of the joint, have come to me for treatment. Of these, 33 were not tuberculous, and in 4 cases the diagnosis is not yet safe. The remainder were positively tuberculous.

Tuberculin in Diagnosis and Treatment of Surgical Tuberculosis.

Dr. R. Tunstall Taylor, Baltimore, summarizes his paper practically as follows: The *x*-ray is the best aid to the clinical diagnosis of tuberculous bone disease. The subcutaneous injection of large doses of tuberculin (1 to 5 milligrams) in children is to be condemned for diagnosis; it is unnecessary, with the other means at our disposal, because harmful and possibly dangerous. Patients with syphilis and leprosy also respond to these large doses. The ocular tuberculin test may cause corneal ulcers and serious eye inflammations in 2 per cent. of the cases, and is, therefore, not to be used from choice. The von Pirquet skin reaction is reliable, safe and valuable, especially in conjunction with the clinical symptoms and the *x*-ray, in children. Tuberculin TR. in doses of from 1/1000 to 1/500 mg. and the fresh-air treatment should be used as a routine in all tuberculous bone and joint cases in an endeavor to immunize the patient. Thorough fixation and traction in all acute cases, and in the spine hyperextension, in addition, are of the greatest importance in treating the local disease. Hyperemia and bismuth paste are valuable additions to treatment. Tuberculous secondary abscesses should not be opened, unless there is some decided reason therefor, and, if opened, should be immediately sutured tight after the pus is evacuated. Otherwise a secondarily infected sinus will surely result, with its train of unfavorable symptoms. Operations on the joints of children should be avoided if possible. Not so with adults.

Discussion on Tuberculosis.

Dr. A. Duval Atkinson, Baltimore: The cases reported by Dr. Hoke, in my opinion, are due not so much to gastrointestinal intoxication as to infection through the tonsils. It has been proved in the last three or four years that the tonsils bear a close relationship to the joints, especially to all inflammatory conditions of the joints. I believe if Dr. Hoke would remove the tonsils by a thorough dissection in the beginning of these cases he would get quick and permanent results.

Dr. William J. Butler, Chicago: The tuberculin test, as all other reactions having their basis on immunity, must be considered as a systemic reaction, and as diagnostic only in this direction, and as not diagnostic of a local organic condition. In order to aid in the local diagnosis in tuberculous affections, as in joint lesions, the opsonic index, if employed following massage or other measures to increase hyperemia around the joint, may add greatly to our knowledge. In cases of glandular tuberculosis in which operation has been performed, recurrence taken place and tuberculin treatment instituted, the scars will frequently diminish and soften, so that the overlying scar tissue is freely movable over the underlying tissues.

Dr. Seale Harris, Mobile, Ala.: Regarding the cutaneous reaction, I had the opportunity of following a case with Dr. White at the Mobile City Hospital. A man was brought unconscious to the hospital, and the question of cerebrospinal meningitis came up. The cutaneous reaction was positive, and the man died a few days later. Autopsy showed that he had died from a cerebral hemorrhage, the result of syphilis. There was no trace of tuberculous infection anywhere in that man.

Dr. Taylor: I did not understand whether Dr. Hoke applied the guinea-pig test in these cases or not.

Dr. William Litterer, Nashville, Tenn.: The guinea-pig test is not only certain, but safe. The mere absence of the tuberculin reaction does not prove anything, although a positive finding after a subcutaneous tuberculin test is of distinct value. I have used the Calmette test in forty-five or fifty cases. In one instance a corneal ulcer followed the test, and since then I have abandoned it. I have found after using the subcutaneous test, making, say, three injections and getting a negative result, that if I then used the von Pirquet test I would get a positive result in every instance.

Dr. Owen, Atlanta, Ga.: Dr. Vaughn used the Calmette test on twenty medical students, and got positive results in six. Three weeks later the test was repeated and 57 per cent. gave positive results. The reason for this was that the patients had simply been sensitized. Dr. Vaughn found the same thing after injecting egg albumin. For instance, he injected guinea-pigs with egg albumin, and subsequent injections produced instant death.

Dr. M. Hoke: There was no trouble with the throat or tonsils in the thirty-three non-tuberculous cases. The bismuth paste has proved of value in some cases, but in others it has failed to do any good. I find that pure tincture of iodin injected into these sinuses is an exceedingly valuable remedy.

Dr. R. T. Taylor: Syphilis has been known to give a positive reaction to the skin test in cases in which the subcutaneous method was used. Syphilis responds to large doses of tuberculin.

Tumors of the Thorax with Abdominal Symptoms.

Dr. A. Duval Atkinson, Baltimore: Acute inflammatory diseases of the pleura and lung, of the pericardium, endocardium and myocardium, of the arterial system, especially of the transverse and descending aorta, and at times of the venous system within the thorax, at one time or another during their course may give rise to the following abdominal symptoms: Tenderness, either confined to a portion of the abdomen or to its whole surface; rigidity of the abdominal muscles; the respiration is of the costal type, and generally it will be found, if the hand is placed on the abdomen, that the spasm will relax momentarily at some time during inspiration; nausea, vomiting, distention, constipation. Fortunately there are some distinguishing features which are characteristic between this condition and peritonitis, especially if due to an acute pulmonary condition like pneumonia, namely, the relative disparity between the pulse and respiration. Often the respirations will register 40 a minute, while the pulse will be about 100. In addition, the respiration will usually exhibit that characteristic catch so commonly seen in pleuritic conditions. Another important point is the decidedly superficial character of the abdominal pain. Superficial palpation may elicit great pain, while really deep palpation may be permitted, even in children. It is of cardinal importance invariably to make a most thorough and careful examination of the thorax in all cases of abdominal lesions serious enough apparently to require operative interference.

DISCUSSION.

Dr. I. I. Lemann, New Orleans: I think every one has been struck by the frequency of abdominal pain in cases of pleurisy. In one case in which the patient was suffering from what appeared to be an alarming condition of the abdomen, I discovered a pleurisy, strapped the side, and the distressing symptoms cleared up in an hour.

Dr. H. L. Sutherland, Rosedale, Miss.: In a young man in whom a diagnosis of gall-bladder disease had been made, careful examination revealed lobar pneumonia.

Dr. J. A. Witherspoon, Nashville, Tenn.: I have seen abdominal pain a feature in pneumonia, empyema, acute plastic pleurisy, and mediastinal tumors. In one case a surgeon had diagnosed gallstones. An examination prior to operation revealed an empyema, but the surgeon was so sure of gall-bladder trouble that he operated, anyhow, and found a healthy gall bladder.

Dr. William J. Butler, Chicago: It has been found that in inflammatory changes in the abdomen there is an increased sensitiveness of the skin over the site of the inflammation, when compared with a corresponding area on the other side. This is especially valuable in gall-bladder affections and in appendicitis.

Dr. R. Tunstall Taylor, Baltimore: In considering abdominal pain we should bear in mind, when dealing with children, the abdominal pain is due to disease of the spine.

Dr. A. D. Atkinson: An interesting discussion is going on in this country and abroad in regard to the sensibility of the peritoneum. I rather think we can agree pretty thoroughly with Lennander, who did more work on this subject than any one else, that the visceral peritoneum is insensitive, but that the perietal peritoneum is extremely sensitive.

A Quick Method of Curing Beginning Gonorrheal Urethritis.

Dr. Edgar G. Ballenger, Atlanta: After having emptied the bladder the meatus is well washed with soap, and the anterior urethra is about half-filled with a 6 per cent. solution of argyrol with a blunt-pointed syringe. The sides of the meatus are compressed, the syringe removed, and the end of the penis thoroughly dried with sterile gauze. A piece of zinc oxid adhesive plaster, about an inch square, previously prepared, pressed against the meatus while its lips are being held closely together, seals the solution in the urethra. The solution is allowed to remain in the urethra for from three to four hours. Two such treatments should be given each day for two days, one on the third day, and a daily irrigation administered for two or three days longer. I have been surprised at the success attained by this method, and I believe the principle a rational one, which will prove of value to all who use it with discretion.

Symptomatology of Prostatitis.

Dr. William Cullen Bryant, *Atlanta*: The classical symptoms of acute prostatitis are apparent in every case, and the condition is easily recognized. On the other hand, the symptoms of chronic prostatitis are very varied, and it is necessary to classify them. I prefer the classification suggested by Young, of Baltimore, namely, urinary, sexual and referred. The urinary and sexual symptoms are well known, but to understand the referred symptoms it is necessary to study the nerve supply of the prostate. The prostate receives its sensory spinal fibers through the pudic nerve and sympathetic fibers from the hypogastric plexus. Through the influence exerted on the highly specialized and sensitive nerve endings in the prostate and prostatic urethra by the pathologic conditions resulting from chronic inflammation, painful impressions are carried along the afferent sensory fibers and by an irradiation or sort of overflow are felt in the area of distribution of those somatic sensory fibers taking origin from the same spinal segment as the visceral sensory fibers supplying the prostate. Thus we can readily understand the meaning of intense pruritus and through the inferior hemorrhoidal, pain in the perineum through the perineal, and the very frequently disagnosed sciatica and lumbago through the nerves coming off from the sacral and lumbar plexuses. Cases have been reported in which the symptoms simulated renal colic so closely that nephrotomy was performed and no stone found, the patients being afterward cured by prostatic massage.

Technic of Operation on Varicocele.

Dr. J. M. Jones, Atlanta: In cases of very large varicocele or very long scrotum, simple resection of the veins is not sufficient, and the technic I use is as follows: After resecting the veins by the Bennett-Howse method, a clamp is applied to the scrotum in such a manner as to allow the removal of the redundant portion. Twelve or fourteen silkworm gut sutures are introduced through the holes in the clamp. The ends of these sutures are then gathered into two bundles and clamped with hemostats. An incision is then made with a sharp scalpel through the skin about one-eighth inch from the clamp, the remaining tissues being cut through with strong scissors curved on the flat. The subcutaneous tissues, consisting of dartos and cremasteric fascia, are then sutured with a No. 0 plain catgut continuous suture. The first turns of a surgeon's knot are then made in the silkworm gut and drawn tight. The clamp is then removed, and after waiting a few minutes for the hemorrhage to cease the skin edges are brought together with a No. 0 plain catgut continuous suture. The silkworm gut sutures are then adjusted and the knots completed.

Appendicitis Mortality. Reports of Fatal Cases. Statistics.

Dr. F. W. McRae, Atlanta: Up to Nov. 9, 1908, I have done 574 operations for appendicitis, with 19 deaths, a small fraction over 3 per cent. mortality. These statistics include all my early cases, Grady Hospital work, operations done in home of patients (some living in hovels), private infirmaries, hospitals and sanatoriums, and cover a period of fifteen years. If we deduct deaths which I have included in the statistics due to coexisting or incidental diseases, it leaves 569 cases, with 14 deaths, a mortality of a little over 2 per cent., due directly to appendicitis and its complications following operative treatment.

Appendicitis in the Negro.

Dr. S. T. Barnett, Atlanta: This subject was first called to my attention by reading Dr. Kelly's work, in which he made the statement that appendicitis in the negro is practically unknown, citing a number of authorities. It happened at that time that I had had a series of four or five operations for appendicitis in the negro which were so typical and the pathologic findings of which were so characteristic that I could only believe that Dr. Kelly had been misinformed, that the disease was practically as frequent in the one race as another. I also wish to refute a statement that has been made that when the negro does have appendicitis the mortality is excessively high. I have removed the appendix from the negro twelve or fifteen times, and so far with a mortality of zero.

Other Papers Read.

Other papers read were as follows:

"Conservation of Energy and Multiple Operations in Surgical Work," Dr. R. R. Kime, Atlanta; "Some of the side Lines or Auxiliaries to the Surgeon," Dr. Shelby C. Carson, Greensboro, Ala.; "Tumors of the Bladder," Dr. A. L. Fowler, Atlanta; "Spinal Injuries, Real and Otherwise," Dr. W. W. Crawford, Hattiesburg, Miss.; "Traumatic Epilepsy," Dr. J. L. Crook, Jackson, Tenn.; "Recent Development in My Method of Treating Structural Scoliosis—Exhibition of Apparatus," Dr. Michael Hoke, *Atlanta*; "Treatment of Habitual Scoliosis by Passive and Active Correction," Dr. Theodore Yoepel, Atlanta; "Results Obtained with Vaccine in Chronic Infection," Dr. J. E. Paullin, Atlanta; "Report of Case of Erysipelas with Fatal Complications," Dr. Z. B. Chamblee, Birmingham, Ala.; "Treatment of Fistulous Tracts and Abscess Cavities by the Vaselin-Bismuth Paste Method," Dr. C. R. Andrew, Atlanta; "Radical Anorectal Surgery without General Anesthesia," Dr. A. B. Cooke, Nashville, Tenn.; "Urethral Stricture," Dr. W. L. Champion, Atlanta; "Anatomy of the Peritoneum and Gastrointestinal Tract from Standpoint of Development," Dr. W. B. Armstrong, Atlanta; "Intestinal Obstruction, Abstracts, Classification, Etiology, Symptoms, Surgical Treatment," Dr. I. J. Sellars, Birmingham, Ala.; "Postoperative Ileus, Early and Repeated *Operations for* Relief, with Report of Cases," Dr. F. G. Cole, Mobile, Ala.; "Pellagra and Pellagraias," Dr. J. H. Randolph, Chattahocchee, Fla.; "Two Cases of Acute Cardiac Aneurism of Unusual Location and Rare Etiology," Dr. G. S. Bel, New Orleans; "Some Neglected Things in the Child's Development," Dr. M. McH. Hull, Atlanta; "*Nature and Treatment of* Neurasthenia," Dr. S. T. Rucker, Memphis, Tenn.; "Neurasthenia," Dr. H. M. Folkes, Biloxi, Miss.; "Nature and Treatment of Functional Neurasthenia," Dr. E. M. Hummel, New Orleans.

The officers elected were named in The Journal, November 21, page 1792.

Book Notices

Religion and Medicine. By Elwood Worcester, D.D., Ph.D., Samuel McComb, M.A., D.D., and Isador H. Coriat, M.D. Cloth. Pp. 427. Price, $1.50. New York: Moffat, Yard & Co., 1908.

The object of this book, as stated in the introduction, is "to describe in plain terms the work on behalf of nervous sufferers which has been undertaken in Emmanuel Church, Boston." It discusses the treatment of functional nervous disorders, and the authors say: "We make free use of moral and psychical agencies, but we do not believe in overtaxing these valuable aids by expecting the mind to attain results which can be effected more easily through physical instrumentalities. Accordingly we have gladly availed ourselves of the services of the skilled medical and surgical specialists who have offered to cooperate with us, and we believe that our freedom in this respect and the combination of good psychical and physical methods have had much to do with our success." The authors have confined their practice to that large group of maladies which are known as functional disorders, "because disorders of this nature are peculiarly associated with the moral life. An attack of typhoid fever may spring from no moral cause and it may have no perceptible influence on the character, but neurasthenia, hysteria, psychasthenia, hypochondria, alcoholism, etc., are affections of the personality. They spring from moral causes and they produce moral effects." In the tracing of this class of disorders to the personality rather than to the person, to moral rather than to material causes, lies the keynote of the success which attends the various systems of faith-healing, and no greater defense against their incursions can be found than a recognition and application of this fact by the medical profession and the public. Janet's method of bringing the obsessing idea "into the field of consciousness" as the first essential toward overcoming its effects, is a scientific application of this principle.

The present work is an exposition of what is known concerning the so-called subconscious mind, suggestion, autosuggestion, heredity and environment as causes of nervousness, the diseases of the subconscious, the nature and therapeutic value of hypnotism, fear and worry, etc. It is a work from which the practitioner, as distinguished from the specialist in psychiatry, will gain as much practical assistance in the comprehension of the personal factor in disease as from more strictly scientific and technical works on the subject.

When we come to the work as the symbol of the Emmanuel movement itself, we must confess that we are constrained by a certain hesitation. We are reluctant to discourage a movement which we believe to be established with the most laudable purpose in view, one which undoubtedly is effecting some good, and in all probability is not as yet offset by much accompanying harm. But the fact remains that few among the religious instructors who will sooner or later take up this work are equipped by training or otherwise to conduct such a movement. In other words, the men who started this movement will soon find that they have lost control of it and that it is in the hands of those who do not appreciate its limitations; thus much more harm than good will result.

The wise physician will welcome the assistance, in suitable cases, of the judicious and tactful minister of any religion; but he will shun the aid of one lacking those qualities.

Die Lehre von der Intubation. By Prof. Dr. J. von Bókay, Director of the Stefanie Hospital for Children in Budapest, Hungary. Paper. Pp. 250, with Illustrations. Price, $2.50. Leipsic: *Verlag von F. C. W. Vogel, 1908.*

This work is dedicated to Dr. Joseph O'Dwyer by Dr. von Bókay. The history of intubation is considered from its beginnings and due credit is given to Bouchut for the invention of his method of intubation, called "tubage," which was based on rational ideas and was developed by him in 1858. "Tubage" failed of success only because of the prejudice and unjust condemnation with which it was received by Bouchut's contemporaries, who were loath to abandon tracheotomy for it. A brief biography of O'Dwyer precedes a most detailed relation of the experiments of this genius, which made the difficult procedure of intubation so simple that it has become the property not only of specialists but of all physicians, and which led to the creation of a set of instruments so exactly adapted to the purpose that all attempts to improve them have merely proved aberrations from the true principles of their construction.

The technic of intubation is most elaborately considered, including all of the accidents and injuries which may occur in its performance. In addition to instrumental extubation, the "enucleation" method of Bayeux, in which the tube is expressed from the windpipe and larynx by stripping them from without by pressure on the neck is fully described. The important subject of the damage which may be done the larynx in the introduction, placing and extraction of the tube occupies 49 pages of the work. The first part of the book considers intubation in relation to diphtheritic laryngeal stenosis; the second, intubation for all other conditions creating obstruction in the larynx or upper trachea.

An important feature of the work is the chapter on intubation as an aid to tracheotomy, which has proved most satisfactory to Bókay.

Bókay's enormous experience in intubation and tracheotomy fit him peculiarly to give a clear, logical and elaborate consideration of intubation. His book may be heartily recommended as a model reference handbook on intubation. It omits nothing, is easily read and is designed to help the physician in general practice and the specialist as well by its judicious advice in difficult situations. A translation of this useful work into English is to be desired.

Ueber Appendicitis Waehrend Schwangerschaft und Geburt. Von Gerhard Renvall. Paper. Pp. 117. Price, $1.00. Berlin: Verlag von S. Karger.

In this volume is discussed a topic of vital interest to the general practitioner, the surgeon and the obstetrician, namely, the prognosis and treatment of pregnancy complicated by appendicitis. After reviewing the experience of others, and especially the results of operative interference in cases of appendicitis occurring during pregnancy, the author advances the following propositions as to the indications for emptying the uterus: In diffuse peritonitis in the last stages of pregnancy, or in cases accompanied by severe septic manifestations after the period at which the fetus is viable, the uterus should generally be emptied by *accouchement forcé*, even if labor pains have not begun; and the delivery should be followed by a laparotomy. If labor pains are present, or if the fetus is dead, an evacuation of the uterus should precede laparotomy, at least in the latter half of pregnancy, and also at an earlier stage if circumstances require it. Exceptions may be made in special cases. Twenty-three new cases are reported in detail from the clinic of Prof. Otto Engström of Helsingfors, and two from the practice of Prof. A. Krogius. The book concludes with brief abstracts of 253 cases from the literature and a full bibliography.

Sanatoria for Consumption and Certain Other Aspects of the Tuberculosis Question. Supplement in Continuation of the Report of the Medical Officer for 1905-06, to the Thirty-fifth Annual Report of the Local Government Board, 1905-06. Paper. Pp. 670, with Illustrations. Price, $1.25. London: Darling & Son, 1908.

This is a supplement to the Report of the Medical Officer for 1905-6 to the thirty-fifth Local Government Board of Great Britain. The volume consists of 670 pages, discussing all aspects of the sanatorium question. A discussion of the advisability of the notification of cases of tuberculosis is added, in which both the advantages and disadvantages of compulsory notification are set forth. While no definite conclusion is drawn, it is admitted that although the useful effects of notification are not as yet very apparent, it is too early to condemn the measure. The report is profusely illustrated with tables and plates.

Text-Book of General Bacteriology. By Edwin O. Jordan, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Cloth. Pp. 557, with illustrations. Price, $3.00. Philadelphia: W. B. Saunders Co., 1908.

Jordan's "General Bacteriology" is an unusually well-written text-book. It is destined to occupy a large field of great usefulness because it meets the needs, not only of the medical student, but also of the general scientific student and reader who is interested in the relations of microbes to disease and in their growing importance to agriculture, to sanitation and to many industries. It is needless to say that an exhaustive discussion of all sides of bacteriology is not intended and would have been quite impossible within the compass of the book. It aims to be a general introduction and, with due regard to perspective, bestows emphasis on general principles rather than on special questions, main stress always being placed on the medical side of the subject. We are familiar with no book on bacteriology that will serve so well the needs of the busy physician—and there are many such—who feels a desire to go over again the general subject of bacteriology in the light of the latest advances and additions to our knowledge. A pleasant and profitable task is in store for him, because this book is interesting and stimulating reading and remarkably up to date. The style is clear and crisp. Professor Jordan is not only master of the subject, but also a skilful writer; witness the introduction in which the chief historical facts in regard to the discovery of bacteria and the origin, scope and biologic significance of bacteriology are admirably set forth. One quotation may be permitted: "The new conception of the microscopic underworld which bacteriology brought into biologic science must be reckoned as a conspicuous landmark, and, in so far as it has changed the attitude of man toward the universe, should be reckoned as one of the most important triumphs of natural science." The book bears the scholar's hall-mark. There is an index of names, as yet an uncommon luxury in American text-books. The biographic references are given according to a fixed plan and not in the incomplete and haphazard manner so often seen in our books and articles, even in those with some pretensions to scholarship. The references call the attention of the reader to articles of historical or classical interest, to valuable summaries and to articles dealing with subjects under active investigation or concerning which there is variance of opinion. In the next edition reference should be made to the fundamental but often overlooked work of Denys and his pupils on the mechanism of phagocytosis. To many, remarks concerning such matters as references may seem wholly unnecessary, but they are not trivial, for the careful, conscientious attention to detail exemplified in this book makes for better scholarship and promotes scientific exactness. Writers of medical text-books should use Jordan's book as a model.

Die Lehre von der Kongenitalen Tuberkulose mit besonderer Berücksichtigung der Placentartuberkulose. Von Anton Sitzenfrey, I. Assistenten der Universitätsfrauenklinik und Privatdozenten für Geburtshilfe und Gynäkologie an der Universität in Giessen. Paper. Pp. 156, with illustrations. Price, $1.40. Berlin: Verlag von S. Karger, 1909.

The origin of this treatise is the suggestion of Professor von Franqué to Dr. Sitzenfrey that he should investigate thoroughly the subject of tuberculosis of the placenta with relation to the doctrine of the hereditary character of tuberculosis and the existence of a hereditary predisposition to the disease. The work involved a great deal of investigation and a thorough search of the literature, as is evidenced by the citing of nearly 200 references. The monograph contains 156 pages, with a number of good illustrations. Much new histologic matter is introduced and the general conclusion reached that, although the placentar cases are comparatively few, and although observation indicates that healthy children can be born when the placenta is diseased, nevertheless the rarity with which thorough investigations are carried out on the placenta and the possibility of bacilli reaching the fetus by other channels than the placenta or of their passing through the placenta without leaving any trace of their passage shows this method of infection to be of greater importance than has been generally supposed.

Pathologic Technic. By Frank Burr Mallory, A.M., M.D., Associate Professor of Pathology, Harvard University Medical School, and James Homer Wright, A.M., M.D., S.D., Director of the Pathologic Laboratory of the Massachusetts General Hospital. Fourth Edition. Cloth. Pp. 480, with illustrations. Price, $3.00. Philadelphia: W. B. Saunders Co., 1908.

The text-book of Mallory and Wright is designed as a guide to the making of postmortem examination and the subsequent histologic and bacteriologic investigations. The fourth edition has been carefully revised for the correction of errors and a few changes have been made. A few methods have been omitted and a number of new ones, which have stood the test of time and trial, have been added. Prominent among the added bacteriologic methods are those for the detection and differentiation of the typhoid bacillus, especially when occurring in the feces. Various methods for tissue-staining, as for the detection of glycogen, lime salts and the *Spirochæta pallida* have been introduced. The book is well illustrated and ought to prove of value to practitioners and students, as well as to the pathologists.

Subcutaneous Hydrocarbon Protheses. By F. Strange Kolle, M.D., Author of "The Recent Röntgen Discovery," Etc. Cloth. Pp. 153, with illustrations. Price, $2.50. New York: The Grafton Press.

The author reviews the literature, selects from it such data as he deems necessary for a full presentation of the methods of paraffin prothesis now in use, and combines with them the results of his own experience. He warns against striving for the unattainable; a surgeon can not remodel malformations as a sculptor would clay. He cautions against filling out defects such as saddle-nose at one sitting, stating that the work must be done slowly, giving the injections time to adjust themselves to the tissues before others are attempted. He gives in semitabular form a list of difficulties and dangers to be looked for and avoided, and enumerates the untoward results which are liable to follow imperfect technic. There are several half-tone illustrations showing conditions "before and after," and a complete bibliography is appended.

Spectacles and Eyeglasses, Their Forms, Mounting and Proper Adjustment. By R. J. Phillips, M.D., Late Adjunct Professor of Diseases of the Eye, Philadelphia Polyclinic and College for Graduates in Medicine. Cloth. Pp. 91, with illustrations. Price, $1.00. Philadelphia: P. Blakiston's Son & Co., 1908.

The fourth edition of this little book, which has proved of so much value to opticians and those ophthalmologists who attend personally to the adjustment of the glasses they prescribe, has benefited considerably by revision. It is almost indispensable to one who fits glasses; and familiarity with its contents is advisable for any ophthalmologist since proper adjustment of lenses is one of the essentials of satisfactory refraction. The constant advances made in the art of spectacle-fitting and the many new and perfected methods in the manufacture of bifocals which are being brought forward, make a revised edition necessary. It is gratifying to note that all innovations which possess real merit have been given due recognition in Dr. Phillips' work.

Clinical Diagnosis: By Charles Phillips Emerson, A.B., M.D., Late Resident Physician, The Johns Hopkins Hospital. Cloth. Second Edition. Pp. 686, with illustrations. Price, $5.00. Philadelphia: J. B. Lippincott Co.

This edition embodies a careful revision, in which fully one-half of the work has been rewritten, necessitating a considerable increase in the number of pages. The subject of the bacteriology of the sputum and urine and a number of new illustrations have been added. The book includes many methods which the general practitioner can not employ, but concerning which it is desirable that he should be informed, and this book makes it possible for him to obtain such knowledge conveniently. The volume is well illustrated.

Angina Pectoris. Von Dr. Louis Peiser, Arzt am deutschen Hospital und deutschen Dispensary der Stadt New York. Paper. Pp. 106. Stuttgart: Verlag von Ferdinand Enke, 1908.

This monograph offers an exposition of the subject of angina pectoris and of pseudoangina, together with a consideration of the etiology and diagnosis of arteriosclerosis, to which is attributed the origin of the anginal disease. Peiser regards the pathology of angina vera as identical with that of arteriosclerosis of the coronary arteries. The treatment of both varieties of angina is considered at length, much stress being laid on prophylactic measures.

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Second Series. Vol. xiii. Periodicity-Prussia. Cloth. Pp. 929. Washington: Government Printing Office, 1908.

This volume of the second series of the Index-Catalogue extends from "periodicity" to "Prussia," and includes 5.556 author entries representing 3,250 volumes and 4.851 pamphlets, 7.678 subject entries of separate books and pamphlets, and 40.221 titles of articles in periodicals. It is needless to comment on the value of this monumental work.

Miscellany

Universal Sphygmomanometroscope.—At Janowsky's clinic at St. Petersburg the blood pressure in the upper extremities is determined by comparison of the findings of five different apparatus. These include the Riva-Rocci cuff, the tonometer, the two spring manometeras of Basch and the water manometer of Zipliaef-Janowsky. Privat docent N. van Westenrijk of St. Petersburg has succeeded in combining these various apparatus in a single one in which one mercury manometer answers for all. It is arranged so that the zero point can be adjusted, and it allows comparison of the findings with different technics and registration of the pressure up to 350 mm. mercury. The mercury tube R (Figs. 1 and 3) opens below into the reservoir R', the graduated scale (Figs. 1 and 4) being fastened between the mercury tube and the reservoir. The whole is mounted on a weighted wooden standard. The right hand branching arm of the reservoir R' (Fig. 2) is connected with the tube which forks to the Riva-Rocci cuff E (Fig. 1), the Gaertner tonometer ring D, the Basch contrivance for determining the pressure in the capillaries F, the rubber bulb for determining the blood pressure in the veins G, and the rubber bulb H for increasing the pressure in the glass chamber F. All these are controlled with stopcocks in the tubes. The left hand branching tube from the reservoir R' is connected with the rubber bulb A, which is compressed by a screw lever to increase the pressure (Fig. 1) in the cuff and ring and also in the manometer. The tube B, with its two enlargements and capillary lumen, runs in the groove K, and is brought into connection separately with the cuff, ring, etc., on the other side of the reservoir R', by turning the stopcock C. The apparatus allows the Riva-Rocci cuff to be used for tonometry as well as in the usual manner. The illustrated description is published in the *Mitteilungen der Gesellschaft für innere Med.*, vii, 202, 1908.

FIG. 1.

Fifty Years of Scotch Lunacy Administration.—Fifty years covers a period of many changes in any department of medicine, but in none more certainly than in the treatment of the insane. This is more especially true regarding the Scotch asylums, as they were at the beginning of this period rather behind the rest of the world. According to John Keay, who writes in the *Caledonian Medical Journal*, October, 1908, "during the earlier years of the nineteenth century the condition of the insane of the poorer class in Scotland, whether in asylums or out of them, was just about as bad as it could be." Ignorance and lack of authority for needed reforms on the part of the board of supervision and indifference on the part of the public are assigned as the causes of this condition. It was left to an American lady, Miss Dix, to inaugurate the movement for investigation and reform. The commission appointed reported in 1857, revealing an amount of misery and wretchedness and a callous indifference to suffering which were absolutely appalling. After some opposition a General Board of Commissioners in Lunacy for Scotland was appointed, district boards formed and district asylums erected and many reforms instituted. In the twenty-third annual report of the commissioners in 1881 the most noteworthy changes that had been made were shown to have been manifested in three directions: 1, In the greater amount of liberty accorded to the patient; 2, in the increased attention that is devoted to their industrial occupation; and, 3, in the more liberal arrangements that are made for their comfort. Keay notes further progress shown at the present time in the following respects: The hospital spirit and methods have been introduced into asylums. The scientific study of insanity is encouraged and the institutions have been transformed from asylums for the safe-keeping and detention of dangerous members of society into hospitals for the cure of mentally afflicted persons. Nurses have been especially trained for the purpose, and the introduction of female nurses has contributed largely to the improvement. The asylums of Scotland have not prosecuted original research on insanity to the extent that those in some other countries have, largely because of the insufficient funds and equipment of the individual asylums. To remedy this a laboratory of the Scottish asylums has been established, where important scientific and practical work has been done by Dr. Ford Robertson. The segregate or villa system of asylum-building marks the tendency to approximate as closely as possible the conditions of ordinary general society life in asylum management. Bangour Village, of which Dr. Keay is superintendent, was constructed by the Edinburgh District Board of Lunacy on this plan in 1898. Other Scotch asylums are being arranged in the same manner. The last characteristic of the modern treatment of the insane, as contrasted with that of the last century, is the provision of the care of the patient in incipient cases in special wards apart from asylums. While such wards have not as yet been established in general hospitals, some parochial boards have provided accommodations for a few patients. The benefits have been so manifest that more general extension of them has been provided for. It is proposed to open such wards in connectin with the Royal Infirmary.

The Effects of Thyroidectomy on the Mammalian Pituitary.—P. T. Herring (*Quart. Jour. Exper. Physiol.*, 1908, i, No. 3) sets forth what he considers histologic evidence of the interrelation of function of the pituitary body and the thyroid gland. The effects of the removal of the thyroid on the pituitary have been noted by Stieda, who describes a hypertrophy of the glandular part of the latter after thyroidectomy; and by Rogowitsch, who states that in those animals which survive thyroidectomy the function of the thyroid is taken over and maintained by an increased functional activity of the pituitary. Herring reports very little change of structure in the glandular part of the pituitary body in all of the animals from which he removed the thyroid, but finds histologic alterations in the pars nervosa and pars intermedia, and in the ependymal cells of the third ventricle. These changes, together with results which he obtains from his extensive comparative histologic studies of the pituitary (*Quart. Jour. Exper. Physiol.*, i, No. 2) lead him to the following conclusions:

The pituitary body produces a secretion (other than the internal secretion), which passes through the pars nervosa to enter the infundibular space. Here it combines with a kind of secretion of the ependymal cells, the combined secretions passing to the third ventricle of the brain to become a part of the cerebrospinal fluid. The secretion of the pars nervosa is of a colloid appearance and is markedly increased after thyroidectomy. The most striking changes are manifested in the nervous part of the posterior lobe and in the laminæ forming the floor of the third ventricle. In these situations granular, hyaline or colloid bodies become very numerous." "The significance of these changes is as yet undetermined," and the nature of the colloid of the pituitary and its relations to the active substances of the posterior lobe are unknown.

Indications of a Special Secretion in the Testicles Before Puberty.—Schmaltz (*Arch. f. Mikr. Anat.*, lxxi, No. 1) endeavors to prove that the testicles of young animals are active in producing a special secretion before the age of puberty is attained. This secretion passes out through the walls of the seminiferous tubules and is carried by the dilated lymphatic vessels of the connective tissue stroma. It is of a watery serous nature and does not represent mucoid or fatty degeneration of parenchymatous cells, as has been reported by some, since it gives none of the ordinary reactions for either. The significance of this secretion and its possible influence on the development of the accessory genital organs (prostate, etc.) have not been determined.

Medical Education and State Boards of Registration

COMING EXAMINATIONS.

Virginia: Lynchburg, Dec. 15-18. Sec'y., Dr. R. S. Martin, Stuart.

New Hampshire: Concord, Dec. 29-30. Regent, Mr. H. C. Morrison.

Louisiana October Report.

Dr. F. A. LaRue, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Oct. 1-2, 1908. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of candidates examined was 21, of whom 13 passed and 8 failed. Four reciprocal licenses were granted at this examination. The following colleges were represented:

PASSED.

College.	Year Grad.	Per Cent.
Atlanta School of Medicine	(1908)	83.2
Louisville and Hosp. Med. Coll	(1907)	87.6, 92.8
Louisville Med. Coll	(1907)	84.2

Wyoming October Report.

Dr. S. B. Miller, secretary of the Wyoming Board of Medical Examiners, reports the written examination held at Laramie, Oct. 14-16, 1908. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. Only one candidate, a graduate of Trinity College, Ontario, 1887, appeared for examination and he passed with a grade of 88.3 per cent.

Medicolegal

New and Forceful Arguments Against Courts Having Inherent Power to Require Submission to Physical Examinations Before Trial.

The Supreme Court of Utah says, in Larson vs. Salt Lake City, that, on the question of the inherent power of a trial court to require the plaintiff in a personal injury case to submit to a physical examination before trial by a physician appointed by the court and, for a refusal to comply with the order to dismiss his case, the authorities are in hopeless conflict.

The courts asserting the power have quite generally held that the defendant has not the absolute right to the order, but that the motion therefor is addressed to the sound discretion of the court, and that the application should be made before entering on the trial; that the defendant has not the right to designate the physician by whom the examination is to be made, but that the examination should be ordered and conducted under the direction of the court whenever it fairly appears that important facts concerning the injury are only to be disclosed by such an examination, and that it may be made without injury to the plaintiff's health, or the infliction of serious pain, or indignity to, or an unreasonable or indecent exposure of, his person; and that while the court has no right, in the enforcement of the order, to compel the plaintiff to actually submit to the examination, the court may nevertheless, on the plaintiff's refusal to do so, dismiss the case or delay the proceeding until he complies with the order, or the court may decline to permit any evidence to be given to establish the injury. A few courts have held that, on a plaintiff's refusal to comply with the order, the court may punish him as for a contempt.

In many cases where courts have asserted the power it will be seen that the existence of the power was either assumed or merely asserted. In others, the courts, instead of discussing the source of the power, or undertaking to state by what authority such a power is exercised, have undertaken to give reasons why trial courts ought to have such a power, and why it ought to be exercised by them. The same thing is true of some text-writers.

Whenever the power of a court is invoked, in order that it may be lawfully exercised, it is essential to point to some constitutional provision or some legislative enactment or the common law authorizing it—not necessarily to some express provision or enactment, but to some provision where the right to exercise the power invoked is fairly implied, or where it may be necessarily inferred from the nature and constitution of the tribunal itself. But it was conceded in this case, and it has been many times declared by the courts asserting the power, as well as by the courts denying it, that there is no common-law precedent where such action of the court as here in question was ever exercised by law courts.

There can be no doubt that, in the absence of a statute, a law court is not authorized to compel a plaintiff, before trial, to appear before a notary public, or a commissioner appointed by the court, and there make answer to pertinent interrogatories propounded to him concerning his injuries, or concerning any other material issue in the case. If a statute is necessary to confer such a power on the court, this court does not see from what source it obtains the power to compel the plaintiff before trial to submit his person to a physical examination, and make answers to proper questions propounded to him by the physician making the examination. Or, if a statute is necessary to authorize a court to order an inspection and examination of property before trial, the court sees no good reason why a statute is not likewise necessary to authorize the court to compel a plaintiff in a personal injury case to submit his person before trial to a physical examination. The fact that a party having peculiar knowledge of a matter fails to bring it forward may raise a presumption or justify an inference in favor of his adversary's claim; or, if he withholds certain evidence with respect thereto, the inference may be justified that, if it had been produced, it would have been unfavorable to his case, but it furnishes no basis authorizing the court to make an order requiring him to divulge his knowledge before trial to his adversary, or to supply him with the means of obtaining it.

Furthermore, the power of the court to compel the plaintiff, in advance of the trial, to submit to a physical examination, in order that the defendant may ascertain the extent and character of the injuries and thus qualify witnesses, who may testify concerning them, is one thing. The power of the court, when the plaintiff has testified concerning his injuries, to compel him to exhibit the injured parts to the jury, when to do so does not involve an indecent exposure, is quite another and different thing.

If a plaintiff testifies concerning a wound on his arm, he may, in corroboration of his testimony, exhibit the wound to the jury. He may likewise be required to do so, at the request of the defendant, as a part of the cross-examination and as affecting the plaintiff's testimony. Though the plaintiff does not take the stand, but evidence has been given on his behalf concerning his injuries, he may nevertheless be called by either party and required in a proper case to exhibit the injured parts as corroborating or affecting the testimony which has been given concerning the injuries.

It may be asked why has not the court power to compel a physical examination in advance of the trial, but has power to compel the plaintiff to exhibit his wounds and injuries to the jury at the trial? The answer is simple. It is for the same reason that courts of law could not compel the inspection or production of private papers or documents in the possession or under the control of a litigant, but, if he came into court with the document or paper about him, the court could compel him to produce it. In the one instance the power to compel one suitor before trial to arm his adversary against himself or to furnish him evidence to enable him to maintain or defend his cause was not recognized; in the other, the right of each suitor was recognized to call any person possessed of facts as a witness, and to interrogate him concerning them. The plaintiff may be a witness in his own behalf. He may also be called as a witness on behalf of the defendant. He may be interrogated by either party concerning any fact within his knowledge. If he testifies concerning his injuries and is asked by either party to exhibit the injured parts to the jury, he, when the disclosure does not involve an indecent exposure, may not, any more than a witness on the stand who has been ordered by the court to produce a document in his pocket, decline to do so. The power which a court has to compel a witness to answer all proper questions propounded to him may also be exercised to compel the plaintiff to exhibit the wound or injury of which he testifies for the purpose of affecting his testimony. But to say that the plaintiff shall submit his person to a physical examination, in advance of the trial, in order that those examining him may become qualified as witnesses and be put in possession of facts theretofore unknown to them, is quite another and different thing.

Damages Recoverable for Miscarriage Caused by Injury.

The Supreme Court of Minnesota says, in the personal injury case of Morris vs. St. Paul City Railway Co., that at the time of the accident Mrs. Morris was pregnant, and the injury resulted in a miscarriage. The defendant company asked the court to instruct the jury that "damages in this case must be limited to such physical pain and suffering as was the direct result of the accident, independent of the question of the condition of pregnancy claimed on the part of the plaintiff," and that, "if you should find from the evidence that the act complained of was negligent, and that the accident resulted in a miscarriage, the damage resulting therefrom must be limited to such damages for such suffering and pain as the plaintiff suffered in addition to what she would have suffered and endured had she carried the child to the full period. If it should appear that there was an increased or aggravated mental or physical pain and distress in connection with such miscarriage, in addition to what the mother would have suffered if the child had been born at the proper time, or that her health had been impaired thereby, then she would be entitled to recover for such additional pain and suffering as she endured, in addition to what she would have endured as a consequence of her condition. If you find from the evidence that she did not suffer any additional pain from the miscarriage over what she would have suffered, had she borne the child at the expiration of the period at the proper time, then she is not entitled to recover anything for the miscarriage."

But the rule of damages for which the defendant company contended, the Supreme Court says, finds no support in the cases, and is, in the court's judgment, unsound in principle. It is advanced by Joyce in his work on damages (section 185), but is not supported by the citation of any authority.

At the time of this accident Mrs. Morris was pregnant, but she was in a natural and normal condition of health. The miscarriage resulted from the negligent act of the defendant company, and it should be required to pay the damages which resulted naturally and directly from its negligent acts. The fact that Mrs. Morris would, in the natural course of events, suffer more or less pain and anguish at the birth of her child, could not be properly taken into consideration. It was too remote, speculative, and uncertain to be taken as a basis for estimating damages. Her possible future suffering had no connection whatever with the suffering which resulted from the negligent act of the defendant company.

In other words, the court holds that when an injury to a woman results in a miscarriage she is entitled to recover such damages as will fairly compensate her for the pain and suffering occasioned by the miscarriage, but not for the pain and suffering occasioned by the loss of the child. The pain and suffering which the mother would have suffered when the child was born in the natural course of events can not be deducted from the pain and suffering occasioned by the miscarriage, which resulted from the defendant's negligence.

The verdict in this case, for $4,000, the court says was large; but, in view of the nature of the injuries and the impossibility of measuring the damages in such a case by any exact rule, the court can not say that it was so large as to suggest that it was the result of passion and prejudice on the part of the jury.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal.

November 26.

1 *Relation Between Human and Animal [illegible] with Special Reference to the Question of t[illegible] of Human and Other Types of the Tub. [illegible] Smith, Boston.
2 *Certain Evil Tendencies in Medicine and Surgery. M. H. Richardson, Boston.
3 *Comparative Value of Change of Climate and of Treatment in Sanatoria Near at Hand in Cases of Pulmonary Tuberculosis. C. E. Edson, Denver.
4 [illegible] Trichinosis: with Report of Case. W. R. Steiner, [illegible]
5 [illegible] or Periarthritis of the Shoulder-Joint [illegible] s.) (Continued). E. A. Codman, Boston.

1. Abstracted in The Journal, Oct. 10, 1908, p. 1259.

2. **Evil Tendencies in Medicine and Surgery.**—Richardson is struck by the widespread tendency at present toward hasty and ill-considered diagnosis, as contrasted with the thoroughness displayed in the clinical reports published in 1828 and 1829. He complains of the resort to the knife as the first step rather than the last, that makes, in his opinion, one of the most prolific of the evil tendencies of the time. The results of incomplete study are seen in those operations, which through either incorrect diagnosis or ill-considered indications, prove their own uselessness. He discusses wherein adequate study lies, and—contrary to the usual opinion, that facts are correctly observed, but conclusions drawn are not logical deductions—he believes that, as a rule, the conclusions are correctly drawn, but the observations themselves are incorrect. The extremeness of radical surgery—and this is sometimes more pronounced in strictly medical men than in surgeons—is exemplified by a case of an obscure swelling of the whole right lower extremity, in which the physician proposed, and this to the patient, not the surgeon, that the femoral vein should be cut down on and the thrombus removed. This, Richardson refused to do, as having nothing in common sense, practice, experience or experimentation, to commend it. While realizing that great advances in surgery have been made in the face of bitter, and as we now know unreasonable, opposition, Richardson defends this opposition as essential to wise and sure progress. If the example of McDowell had encountered no opposition there would have been an awful mortality and the progress of modern ovarian surgery would have been set back 100 years. He protests against the tendency toward operative diagnosis as tending to make ordinary diagnosis slipshod and inaccurate.

Medical Record, New York.

November 28.

6 *Differentiation of Outbreaks of Typhoid Due to to Infection by Water, Milk, Flies and Contacts. J. F. Anderson, Washington, D. C.
7 Rocky Mountain Spotted Fever. A. A. Robinson, Ogden, Utah.
8 Impressions Derived from a Visit to the Warm Springs of Virginia. A. H. Buck, New York.
9 Cholecystitis, with Suggestions for Prevention of Gallstones. H. W. Bettmann, Cincinnati.
10 Case of Syringomyelia. L. S. Manson, New York.

3. Abstracted in The Journal, Oct. 10, 1908, p. 1254.

6. **Differentiation of Typhoid Outbreaks.**—Anderson lays down the following characteristics of outbreaks of typhoid due to water:

1. General distribution of cases throughout the areas supplied by a particular water.
2. Explosive onset of the outbreak.
3. Seasonal prevalence: spring or late winter.
4. Comparative freedom from the disease of persons not using the suspected water.
5. Inspection of the watershed shows evident sources of infection.
6. The outbreaks may have begun or ended following a change of the water supply.
7. Bacteriologic and chemical examination reveals evidences of pollution.
8. Exclusion of all other probable causes.

The following points indicate strongly that the infection is being introduced through the milk:

1. Sudden outbreak of an unusual number of cases followed by a rapid decline.
2. The appearance of an unusual number of cases among the customers of a certain dairy.
3. Unusual incidence of cases among users of milk.
4. More cases among the well-to-do than among the poor.
5. The finding of the typhoid bacillus in the suspected milk.

The chief characteristics of outbreaks of typhoid due to transmission by flies and by contact are their local character, their appearance in places where the sanitary conditions are poor or where they are neglected, occurring during the fly season, in the case of fly transmission and among those most closely associated with the patient. There have been reported in the literature many interesting outbreaks of typhoid due to conveyance of the infection by oysters and other shellfish, fruits, vegetables, ice cream, watercress, celery, ice, etc.

12 *International Classification as Applied to Morbidity Returns. C. F. Mason, Washington, D. C.
13 At What Age Periods and in What Measure Has the Reduction in the Mortality Rate from Tuberculosis Manifested Itself in the City of New York During the Past Forty Years? W. H. Guilfoy, New York.
14 *New Method for the Transfusion of Blood. R. T. Frank, New York.
15 *The Public Health Plank. C. E. Wood, Chicago.
16 *Iron (Concluded). J. Knott, Dublin, Ire.
17 Adiposis Dolorsa with Involvement of Large Nerve Trunks. P. N. Bergeron, Philadelphia.

11. **Antituberculosis War.**—Knopf describes the work done by the German Red Cross in the fight against tuberculosis

and urges activity of the American Red Cross in the same direction. He pleads for support for the Red Cross Christmas stamp (see THE JOURNAL, Nov. 14, 1908, p. 1720), and believes that it will lead to a tuberculosis sanatorium with a pavilion for every state.

12. **The International Classification.**—Mason suggests the adoption of the international classification of the causes of death in use in the Army since 1904 for morbidity uses. He reproduces the tables with certain suggested changes

14 **Transfusion of Blood.**—Frank describes in detail a new method of transfusion at present tried only on animals. It consists essentially of the use of a link, made from the carotid of a dog, between the artery of the donor and the vein of the recipient, instead of dissecting out and uniting the two vessels directly. Frank has shown that an animal blood vessel does not tend to induce clotting during the transfusion.

15. **Public Health Plank.**—Wood discusses the proposition to create a public health department and urges in opposition thereto the Hepburn bill for the extension of the duties of the U. S. Public Health and Marine Hospital Service. He quotes almost *in extenso* a paper on the Public Health and Marine-Hospital Service by Surgeon G. B. Young.

16 **Iron.**—Knott concludes a learned dissertation on iron, metallic and magnetic, physical and philosophic, its place in mythology, demonology, astrology, and in medical and surgical therapeusis, which was begun in the issue of November 14. His practical conclusions are that our most reliable and clinical data have been furnished by empirical observations—not by scientific experiment or physical demonstration. While iron is specific in the anemia of chlorosis it is not equally trustworthy in other varieties of anemia. To obtain its advantages, the bowels must be kept open throughout. The combination with arsenic, in the author's personal observation, best secures advantageous results. The bird's eye historical view furnishes many instances of anticipation of modern practice. Knott hopes to aid in checking the prescription of 'tonic" iron in the anemia of intestinal irritability of tuberculous disease, to say nothing of the respective associations of fever, infancy and senility.

Lancet Clinic, Cincinnati.

18 *Clinical Conclusions as to the Value of Vaccine Therapy in Surgical Infections J C Hollister, Chicago
19 *Ignorance of the Significance of Middle Ear Disease. H M. Hays, New York
20 Extrauterine Pregnancy. W D Hamilton, Columbus.

18 Abstracted in THE JOURNAL, Oct 31, 1908, p. 1535.

19 **Ignorance and Middle-Ear Disease.**—Hays complains of carelessness in carrying out orders of the general ignorance of the seriousness of ear conditions, aside from pain and discharge, and of fear of operation. The last is largely eliminated in large cities: the two former factors disappeared only when a pain in the ear becomes to patients as significant of possible mastoid disease, as a pain in the right side is of appendicitis

Medical Fortnightly, St. Louis.

November 25

21 *The Prostate as a Factor in Nervous Disease. J L Boehm, St Louis
22 Threapeutic Treatment of Typhoid from Beginning to End C. F Wahrer, Fort Madison, Ia

21. **The Prostate and Nervous Disease.**—Boehm discusses syphilis of the prostate, the relation of the prostate to the spinal cord, neuralgia of the prostate, sexual neurasthenia, the medical aspect of rape and criminal assault, and the medicolegal state of sexual perversion. He concludes as follows:

1 The prostate and its appendages when diseased have a special influence on the nervous system, in close similarity to the nervous sequelæ of the diseased female pelvis

2 The prostate and seminal vesicle are to the neurotic male what the uterus and tubes are to the female, and must always be carefully examined in neuroses

3 Apparently simple disturbances of the prostate may cause serious reflex neurotic conditions, because of the complexity of the nervous mechanism surrounding and supplying it

4 The question of an internal physiologic secretion, and the possibility of the lecithin and organic constituents of prostatic secretion serving as a nutritive factor to nerve metabolism, has not yet been scientifically determined.

5 Spinal asthenia and cerebral exhaustion are commonly and often ascribed to overwork at the office or in literary pursuits, but not always recognized as dependent on a diseased prostate

6 In cases of sexual crimes and criminal perversion, an intrapelvic and extrapelvic examination of the genitalia of the accused should be made by expert urologists, at the same time that the expert neurologists examine the mentality of the accused

7. Jurists should recognize the mental condition of the fiend or pervert who commits sexual crimes, as not always due to a hereditary taint, but probably as commonly the result of some previous urethral disease, uncured at the time. From this chronic diseased condition sexual mania results

8 There is a medical aspect to the recent lynchings and riots, because the fiends responsible for them are diseased and are not human monstrosities Temporary sexual insanity is a reality as much deranged mentality caused by typhoid fever or some condition of hyperpyrexia.

27 Reactive Cell Proliferation in the White Rat; and Its Relation to the Genesis of Transplantable Tumors. I. Levin, New York
28 Factors in the Physiology and Pathology of Gastric Secretion. N B Foster and A. V. S Lambert, New York.

23. **Lesions of Adrenal Gland.**—Pearce shows that hyperplasia of the adrenal is an almost constant lesion in arteriosclerosis associated with chronic interstitial nephritis and left-sided hypertrophy, and that it occurs with almost equal frequency in arteriosclerosis with chronic nephritis of the parenchymatous type, and that it is also a frequent lesion of arteriosclerosis without nephritis and of nephritis without arteriosclerosis. Adrenal hyperplasia is consequently probably the result of some factor active in a period of life in which these affections are most frequent. The adrenal lesion consists of increase of connective tissue, round cell infiltration, increase in the thickness of the vascular wall and hyperplasia of the adrenal cells proper.

25. **Catalase in Human Tissues.**—Winternitz and Meloy find that the catalytic activity of human tissues varies greatly in disease. In nephritis the kidney always shows the most marked reduction in its power to decompose hydrogen peroxid, although other tissues, including the blood, may also show some decrease in this power. The activity of the blood in two cases of eclampsia was not reduced, and this is regarded as an important fact, because if it can be substantiated it will furnish a ready means of differentiating between eclampsia and nephritis.

41 Silverized Catgut—The Argyrol Method. T. R. MacClure, Detroit

29. **Ethyl Chlorid.**—Lee discusses the use of ethyl chlorid in general anesthesia on a basis of 5,575 cases between December, 1907, and June, 1908. It was used alone in 947 cases, with ether in 4,148, and with various other anesthetics in the remaining cases. The youngest patient was 24 hours old, the oldest 84 years old. The fatalities were 5, all of them occurring when ethyl chlorid was used alone. The fact that the ethyl chlorid was given first and in all the cases in which

the patients were considered bad anesthetic risks distorts the statistics. Three deaths occurred under ether during its administration alone in 1,444 cases. The facts that ethyl chlorid can produce deep anesthesia in from 15 to 20 seconds, and that its danger signs are so easily overlooked, are emphasized. In alcoholics and some others it produces muscular spasm and rigidity. Its advantages, however, are tempting. There is no respiratory irritation, its action is rapid and the lessening of the amount of ether requisite in combined anesthesia saves the excretory organs. It is still used in the hospitals for minor surgical procedures, the dressing of the more painful wounds, and in combination with both ether and chloroform.

31. **Breast Tumors in Childhood.**—Jopson, Speese and White conclude that breast tumors, though rare in childhood, occur in both sexes and at all ages. The benign tumors are more frequent than the malignant tumors. Fibroepithelial growths are most common, then angiomata. Sarcoma occurs, but is rare. Carcinoma hardly ever occurs before puberty. Girls are more frequently affected than boys. Angiomata are commonly congenital; fibroadenomata develop with the approach of puberty. The small benign tumors occasionally cause no inconvenience. At other times, pain, tenderness, or discomfort from excessive weight or size are present. Sarcomata usually present their customary symptoms. Operation is usually indicated in the benign and always in the malignant varieties. In small benign tumors or those involving only limited areas, conservative plastic operations with preservation of breast and nipple are indicated; in a goodly number, however, the breast must be sacrificed. The axilla should be cleaned if it contains enlarged glands. The results of operation are good.

34. **Kidney Infection in Apparently Healthy Persons.**—Cobb points out that it is not well understood by the profession, that in persons apparently in good health septic infarcts of the kidney may be caused by bacteria, usually colon bacilli, circulating in the blood, and that the acute cases of this form of hematogenous infection can present a typical picture of certain of the grave abdominal emergencies—appendicitis, cholecystitis or visceral perforation, with abdominal tenderness and rigidity, vomiting, high pulse, temperature and leucocytosis. In persons apparently well the onset is usually acute and without warning. The course of the disease may be rapid, with increasing toxic symptoms, or after an acute onset the patient may go for weeks or months in a septic condition. The very acute cases are the ones which simulate most closely abdominal infections.

35. **Renal and Ureteral Surgery.**—Eisendrath and Herzog discuss multiple ureteral calculi, complicated by hypoplasia of the opposite kidney; renal lipoma *"ex vacuo"*; and rupture of the kidney.

36. **Ankylosis of the Elbow.**—Scudder reports a case of arthroplasty for complete ankylosis of the elbow, in which a year and a half after operation the joint was strong and serviceable—a little loose, but not a flail joint. On contraction of muscles the joint is as firm and secure as a normal one. The power of extension is preserved. The flail joint of an ordinary excision is to be avoided. A stable joint with power in extension is desirable. Power in flexion is naturally present. An arthroplasty preserves power in extension. Arthroplasty is especially applicable to the elbow joint—less so he thinks to the knee and hip.

38. **Fracture of the Neck of the Femur.**—Flint concludes that the conservative aim must as yet consist in an endeavor to obtain ankylosis. There will be some shortening and objective lameness, largely offset, however, by compensating tilting of the pelvis and lumbar curve of the spine. The least desirable result is to have the femur escape from the acetabulum and become displaced upward. The majority of the patients having had an excision will derive benefit, whereas the outcome of a pegging operation is far more doubtful and should therefore be limited strictly to the very few cases.

39. **Fractures of Femur.**—Ashhurst and Newell have studied 121 recent fractures of the femur in the Episcopal Hospital during the last three years, in which conservative treatment was employed of such a various nature as to be fully representative—longitudinal traction by Buck's extension apparatus with and without sand bags. Volkmann's sliding splint, the double inclined plane, Smith's anterior splint, and more complicated appliances. They conclude that, with the exception of four patients, the results of the conservative treatment of fractures of the femur, excluding those of the neck, were satisfactory; and they very much doubt whether operative treatment of such cases could do more than give entirely useful limbs in 90 per cent. of cases, and leave only one out of every three patients with no other functional impairment than a limp.

45 and 48. Abstracted in The Journal, May 23, 1908, p. 1721.

47. **Blood Pressure and Cerebral Hemorrhage.**—Sawyer reports 16 cases of cerebral hemorrhage, in which blood pressure examinations were made, and summarizes practically as follows:

1. Patients with high tension pulse, no kidney lesion, and no previous hemorrhage are least likely to suffer from increased pressure.
2. Patients with kidney lesions which will not respond to treatment or whose blood pressure will not lessen, are liable to fatal uremia.
3. Nephritic patients with increasing blood pressure are especially liable to cerebral hemorrhage.
4. Increased blood pressure without a kidney lesion is more liable to terminate in hemiplegia than the one with such lesion.
5. Nearly half of all patients with increased blood pressure have hemiplegia; 50 per cent. have hemorrhages.
6. A second hemorrhage with hemiplegia due to hemorrhage already existing, but with no kidney lesion, is usually fatal.
7. Patients with nephritis and increased blood pressure are as liable to succumb to the second hemorrhage as to live.
8. Second hemorrhage occurring when both hemiplegia due to a former hemorrhage and nephritis exist are seldom fatal.

From this summary they conclude that while increased blood pressure bears a striking relation to cranial hemorrhage, it must not be used as an infallible sign of such an occurrence, but must be weighed in relation to other existing conditions.

61 Autotoxemia of Pregnancy. H. L. Reddy, Montreal.
62 Cesarean Section. R. E. Webster, Ottawa.

57. **Congenital Myotonia.**—Birt gives an interesting study of Thomsen's disease in his own person. He first discovered it while a medical student, and the diagnosis has since been amply confirmed by experts. The condition consists essentially of a painless cramp, affecting groups of voluntary muscles when an effort is made to bring them into place. There results a sluggishness of action, which, however, wears off if the action continues to be repeated without intermission. In the author's case all voluntary movements are more or less affected, in proportion to the bulk of the muscular group involved. Other authorities to the contrary notwithstanding, Birt is convinced that the following factors are important in regard to the production of cramps: Prolonged rest of muscles; sudden and forcible attempt at contraction; mental excitement and emotion; direction of attention to it; cold and fatigue tend to aggravate the spasm at inception of movement. Small doses of alcohol diminish its severity. He considers that the disease is primarily a congenital functional defect in the mechanism of inhibition. Owing to the faulty functioning of the neurones concerned, the muscles at rest are kept in a state of hypertonus, and on attempting suddenly to contract a muscular group, the inhibitory "brake," so to speak, can not be taken off rapidly enough. This delay would represent the prolonged latent period and the moderately slow contraction. On attempted relaxation the disorder of inhibition is more than ever in evidence—the "brake" is taken off with greatly increased difficulty, and thereby is explained the persistence of the contraction and the remarkedly slow relaxation. The more powerful the contraction, the greater the inhibitory difficulty. The hypertrophy of the muscles would thus be a secondary development, dependent (a) on the state of hypertonus (kept up by the overactivity of the inhibitory mechanism) during rest; and (b) on the prolonged contractions and delayed relaxations constantly repeated. It is conceivable that the trouble might be aggravated by the excessive accumulation of the products of muscle waste during the prolonged contractions. This view would make the defect in Thomsen's disease comparable to that in stammering, and class it as a neurosis of the whole psychomotor tract. It accounts easily for the aggravation caused by depressing mental emotions, cold and fatigue, and the relief under the opposite conditions. The wearing off of the spasm on repetition of the movements would be explained by a rapid exhaustion of the excessive inhibitory impulses; and the early fatigue by the excessive accumulation of the products of muscle waste. The longer the period of rest, the greater the rapidly renewed power of the inhibitory "brake," and, consequently, the greater the tonic spasm on voluntary movement requiring powerful willing to overcome it. Birt is convinced of the important rôle played by the nervous system. Too little stress has been laid on other neuroses in the different family groups. In his own case, one sister deceased, showed it in a severe general form, one suffers from traces of it and two male maternal cousins also suffer from it; the nervous element predominates in the family. As regards prognosis, two points are of importance: First, the earlier in youth the diagnosis is made the more important in the choice of an occupation; and second the subjects are in more than ordinary danger of accident, as the sudden movement to get out of harm's way is often impossible. In treatment, nothing has proved of any avail.

63 *Sociologic Medicine. J. Ullman, Buffalo.
64 *Municipal Contagious Disease Hospitals—Their Medical and Financial Importance to the Community. R. J. Wilson, New York.

63. **Sociologic Medicine.**—Ullman emphasizes the need of a public health department in the cabinet, discusses the mortality of infant life, the newspaper alliance with quackery, the teaching, not only of hygiene and philosophy, but of social science and economics, in schools, the tenement evil, factory evils, the social evil, and the Food and Drugs Act. He points the moral of sociologic medicine as follows: The lesson must be brought home to the people, that they are responsible for much of the disease and suffering, and so it is now important to study the relations of home surroundings to disease.

64. **Municipal Contagious Disease Hospitals.**—Wilson urges the importance to communities of municipal contagious disease hospitals, and cites the Willard Parker Hospital in New York as an evidence of their importance and value. He discusses the cost and the economic relations of the hospital, and as to its situation he says it is not necessary to hunt for some secluded spot; the hospital should be so centrally located that ambulance calls will be as short as possible. The appellation, pest house, is responsible for much expense and distress. It calls up to mind loathsome things, things dangerous, to be avoided, and to be afraid of. Contagious diseases are not loathsome, and are not more dangerous when properly administered than other communicable diseases.

92 Papilloma of the Larynx in Children. J. P. Clark, Boston.
93 Diagnosis of Otitic Brain Abscess. T. Heimann, Warsaw.

91. **Black Hairy Tongue.**—Blegvad gives an exhaustive study of black hairy tongue (*lingua villosa nigra*), based on 128 cases by 88 authors, to which he adds 10 cases from the Municipal Hospital of Copenhagen. On the back of the tongue of an otherwise healthy individual is found a brownish-black spot, just in front of the circumvallate papillæ and extending forward to about one inch from the tip. The spot is symmetrically arranged on each side of the median line, and the borders and tip of the tongue are covered with a whitish fur. The spot owes its appearance to long hairs, the prolonged papillæ filiformes. These have a length of from ¼ to ½ inch and are longest posteriorly and on both sides of the sulcus medianus linguæ. Thus the middle of the tongue may appear very deep as though defective. The surface of the tongue can be compared to a wet, long black-haired dog, or to a wet silk hat. The hairs are directed forward, and if the tongue is rubbed in the opposite direction the appearance just mentioned is noticed. The surface of the tongue is slimy and on the base and between the papillæ vallatæ there is a whitish fur that resembles thrush. On scraping the black spot the prolonged papillæ are easily cut off and do not leave a bleeding surface. They are conical, are black only at the apex of the cone, thick and gray at the base, and float in an opaque mucous fluid. The disease often presents no symptoms. At other times disagreeable and severe symptoms are present—dysesthesia and paresthesia of the tongue; sensation of dryness, tickling, etc., sometimes pain in the tongue or the gums; in some cases taste is weakened, in others increased to the extent of pain; *fetor ex ore.* Sometimes it lasts a few days, sometimes several months or years. Black tongue is only a symptom that in certain conditions accompanies different and acute chronic diseases. Blegvad discusses the pathology and says that he tried to cultivate a mould from the tongue, but while in all cases colonies of white and gray micro-organisms developed, there were no black or brown moulds. He discusses the etiology at considerable length and expresses his opinion that the disease originates in those persons with normally well-developed filiform papillæ which have become prolonged and stained from without. The hypertrophy may be due to irritation, nutritive disturbance, mouth-breathing, perhaps bacteria. The coloring he considers due to food and wine, tobacco, especially chewing, and drugs. Mouth-breathing may also play a part. He insists on the importance of tobacco in the etiology, and suggests the use of opium as a possible cause. He does not consider that there is any essential difference between black tongue and the ordinary furred tongue.

1. **Examination of Urine.**—Foxwell discusses the physical, chemical and microscopic examination of the urine, and points out that such occasional examination is apt to be fallacious when individual findings are relied on, since all healthy organs can do work considerably beyond what they are normally required to do. He uses a system of average analyses, and as the result of a series of investigations made in patients suffering from various diseases, he considers specific gravity 1012, amount 50 ounces, urea 1.4 per cent., 310 grains, as the lowest average analysis which would enable a man to go about doing a moderate amount of work in the world. The lowest which would enable a man to get up and do light work which did not necessitate regular attendance, he considers 1011, 45, 1.2, 238, for such a man would often be invalided; while an analysis as low as 1010, 40, 1.0, 175 would necessarily confine him to bed; or if he got up, his manufacture of waste material would be greater than his removal of it, so that often severe breakdowns would occur, during which his nitrogenous intake would have to be of the smallest to enable equilibrium to be once more established. This is for men. Women would have a smaller excretion, but this decrease is shown, not in the strength of the solution, but rather in its amount. For the women with healthy kidneys had an analysis of 1019, 28, 1.8, and the men of 1019, 39, 2.1. The female kidney does work of equal quality, but of smaller quantity. There is nothing more striking than this maintenance of quality by the healthy organ; if there is less urea to be excreted, then the quantity of urine is lessened, not the strength of the solution. Hence the urea percentage and the specific gravity are the two important factors which indicate the degree of kidney damage. A patient with damaged kidneys promptly calls on the heart for aid, and his strength depends on the functioning power of both these organs, and not on the kidney alone. The increased cardiac action, by increasing the flow of blood through the kidneys, will enable these to secrete a greater quantity in any given time and so make up for the lessened quality.

3. **Operation for Malignant Tumors.**—Manders discusses the combined surgical and electrical treatment for cancer by Keating-Hart, termed by the author sideration (treatment by flashes) and renamed by Poggie "fulguration." The novelty in fulguration consists in the application of oscillatory electricity in combination with actual surgery. He describes the Keating-Hart apparatus and the two methods used, incorrectly termed bipolar and unipolar, respectively. Manders adds a third or intermediate method, not mentioned by Keating-Hart or others, in which the patient is treated by one phase and the other is supplied from the floor, walls, etc., of the room by connecting the proximal end of the inductance coil to the earth. The operation is divided into four stages: 1. The surgeon divides the tissues and lays bare the neoplastic masses without separating them. 2. The tumor is fulgurated by the strongest sparks so as to produce the greatest possible effect in the shortest time. The duration of this is from "a few minutes up to ten." 3. The surgeon excises the growth. 4. Fulguration again. Manders discusses the views of various authors and enumerates the demerits of the method, and adds: If fulguration has in any way reduced to a minimum the recurrence of cancer after operation the combined operation is fully justifiable and must be regarded as a distinct gain in treatment. The disadvantages, he says, may be obviated by a new method which he terms electroscision. The essence

of the technic is the utilization of the continuous and undamped oscillations of electricity instead of the intermittent and rapidly damped trains of oscillations employed in the production of fulguration. The principal differences between the two are that in fulguration the spark really resembles forked lightning in its discharge, for a violent stream of sparks springs from the electrode to the most salient points opposed to it, so that it is possible for a germ lying in a sulcus, or even well in the open, to escape its destructive influence. Like lightning, too, the spark is intermittent. Just as the condenser cloud has to be charged up again to the breaking point before another flash can occur, so must time elapse until the Leyden jars are again recharged by the coil or by the transformer, whichever is used. He describes the apparatus, which is extremely simple and much less cumbersome, and refers for a technical description to the *Journal of the Roentgen Society,* No. 17, Vol. 4.

4. **Tabes Dorsalis.**—After discussing the pathology of this condition, Robertson states that the facts recently observed have served to establish more securely the conclusions that general paralysis and tabes dorsalis are dependent on the presence of specific infective foci, primarily localized in the nasopharyngeal and oral mucosæ in the one case and in the genitourinary tract in the other, and that in both diseases the bacterial and toxic invasion is essentially lymphogenous, as maintained by Orr and Rows on the ground of their experimental work.

5. Abstracted in The Journal, Oct 17, 1908, p. 1359.

British Medical Journal, London.

13 Mental Cripples G. H. Savage
14 *Tuberculosis in Limeworkers. E J B. Selkirk.

8 **Arteries.**—MacWilliam and Mackie have microscopically examined arteries from a large number of specimens, some obtained from amputated limbs after death by accident, drowning, etc., while the others covered a considerable variety of disease conditions. They give diagrams of numerous sections with descriptive notes, and conclude that when death occurs by a relatively gradual exhaustive process the state of the arterial muscle at the time of death may be such that its contractility soon disappears, instead of being capable of persisting for considerable periods, as in many cases of more sudden death and of amputation; though even in the latter cases there are wide variations as regards the behavior of the vessels after death, no doubt depending on varying conditions of arterial muscle at the time. They have not seen decided contractility in the human adult so late as two days after death. In children contractility may persist longer than in adults.

10 **Stokes-Adams Syndrome.**—Turrell and Gibson relate the details of a case under observation for more than eight years, in which, at autopsy, no gross change was present in regions occupied by the bundle of His or its branches Microscopically, there was a tendency to fibrosis in the region of the central fibrous body of the heart, extending downward and encroaching on the bundle. The bundle in the fibrous body itself was represented only by a few isolated strands of muscular tissue.

12. **Infective Processes.**—Cheatle considers the relationship between the nervous system and infective processes under two distinct heads, neurovascular and neurotrophic. He asserts that vasodilatation is not a marked feature of those infective diseases in which limitation to nerve area is most obvious, and that there is some factor of limitation other than pure vasodilatation to be considered in these cases A neurotrophic factor must be taken into consideration in the process of immunity.

14. **Tuberculosis in Lime Workers.**—Selkirk has investigated a general opinion among lime workers that they are exceptionally free from bronchitis and pulmonary tuberculosis. He was unable to find an instance of phthisis among them, nor could he learn on inquiry of any worker in lime kilns having died from tuberculosis. He asks whether those who inhale and swallow much lime are abnormally free from tuberculosis of the lungs. He discusses what is known of the therapeutics of calcium salts, and says it appears that the continued absorption of calcium from the lungs and intestines might maintain an abnormally high percentage of it in the blood. He suggests that the workingman predisposed to tuberculosis might turn his attention to lime and cement working as an occupation, and even hints at the organization of lime works as a curative tuberculosis colony. A rapid increase of weight is commonly observed in new workers at the Warren Cement Works at Hartleypool.

19 *Colostomy by a New Method, with Attempt at Sphincteric Control C Ryall

19 **Sphincteric Control in Colostomy.**—Ryall describes a new method of colostomy, in which the fibers of the rectus muscle are split longitudinally, a stout loop of fibers being detached from the posterior part of the muscle on each side of the line of cleavage. Each loop is then drawn over to the opposite side and made to overlap, the two overlapping loops forming a ring of muscle fibers through which the gut is drawn. The fibers above and below the gut are then brought together with sutures The greatest gentleness is called for. During healing some retraction of the gut takes place, so it is better to err on the safe side and leave a little too much gut protruding; it can be separated later. The author's experience of the control obtained by this method is encouraging, but it remains to be seen whether it will stand the test of time.

21 *Operative Treatment of Puerperal Fever Sir A Macan
22 *Problems in the Treatment of Puerperal Septic Diseases A K Gordon.
23 *Case in which Ovariotomy was Performed During Labor. J B Hellier
24 *Two Cases of Abdominal Hysterectomy for Rupture of the Uterus W. E Fothergill

21. **Puerperal Fever.**—Macan considers this subject under the following heads:

I THE SURGICAL TREATMENT OF LOCALIZED INFLAMMATIONS:
  1 Wounds
  2 Interior of the uterus
II THE EVACUATION OF COLLECTIONS OF PUS:
  1 In perineum and vagina
  2 In pelvic connective tissue
  3 In the abdominal cavity and pelvic peritoneum
III THE REMOVAL OR LIGATURE OF INFLAMED VEINS FOR PYEMIA:
IV THE REMOVAL OF THE UTERUS

The results that have hitherto been obtained by removal of the uterus in cases of bacteriemia occurring in the puerperal state are not encouraging. Three fourths of the patients who were operated on for retention of portions of the ovum after labor at full term died, and one half of those who were operated on for the same cause after abortion; while the mortality—when the indication was severe inflammation of the uterus—whether at full term or after abortion, was 76 per cent. As the general mortality of puerperal fever may be put down at from 15 to 20 per cent., and that of the worst cases 50 per cent., the removal of the uterus, even if confined to the worst cases, which is far from being the case up to the present, increases this mortality instead of diminishing it. The cause of death after the operation is most commonly general peritonitis, which, if not present before the operation is due to an infection of the peritoneum by the lochia, or an extension of inflamation from the stumps, or bacteriemia from these as a center. These dangers can certainly be lessened, and probably be entirely prevented, if proper precautions are taken, and if cases are excluded in which infective emboli are already present in the lungs, liver, spleen, or kidneys, even though the patient's general condition is not desperate. The danger of removal is also lessened by performing Porro's operation with thorough cauterization of the stump.

22. Puerperal Septic Disease.—Gordon reports and discusses cases, and concludes, among other things, that even if suppuration be present in the uterus itself, hysterectomy is not necessarily indicated. In his experience he found sera almost useless, except when the toxemia was intense with but slight evident local lesion. The only harm he ever saw result from their use was an urticarial eruption. For three years, he has been using massive subcutaneous injections of normal saline solution in puerperal infections generally, and in very severe cases, intravenous injections also. For the last year he has added 50 c.c. of polyvalent antistreptococcic serum to the intravenous saline, and has little doubt that it acts better. He explains this by supposing that the serum contains an immune body but no complement, and that the saline injection by producing a leucocytosis supplies the complement desired.

23. Ovariotomy During Labor.—Hellier reports a case in which during labor a tense tumor was found occupying the pouch of Douglas and effectively preventing the head from entering the pelvis. Laporotomy was performed and the uterus was drawn forward out of the abdominal cavity. An ovarian cyst the size of a melon was then very easily drawn up out of the pelvis and through the wound. There were no adhesions. It was attached to the left side of the uterus by a well-defined pedicle, in which the venous sinuses were extremely large. The pedicle was tied in small sections with cat-gut, closing the peritoneum over the stump. The uterus was next replaced, the head being guided and pressed down into the pelvis. The abdominal wound was closed with two series of continuous catgut sutures passed through the deeper layers and twenty interrupted silkworm-gut sutures through the skin and superficial tissues. The abdominal wall was then firmly strapped and bandaged. Labor proceeded naturally without complications.

24. Rupture of the Uterus.—Fothergill reports two cases in which abdominal hysterectomy was performed after completion of labor in which the uterus was ruptured, and comments thereon as follows: The fact that the two patients recovered favors the opinion that when a rupture of the uterus is sufficiently serious to demand the opening of the abdomen, it is safer to remove the organ than to attempt to save it. This view is, or was until recently, unorthodox; but if operators were to publish the results of their recent cases it would probably be proved to be correct. It is indeed reasonable to suppose that the presence of a badly injured puerperal uterus with its impaired blood supply may be a serious menace to the life of a patient already suffering from hemorrhage and shock.

30. Duration of Incubation in Syphilis.—The research on monkeys and rabbits reported shows that the length of the period of incubation is not determined by any cycle of evolution of the *Treponema pallidum* but is due to the slow, progressive development of the histologic changes induced by the proliferation of the microbe. The change of environment at first checks the growth of the microbes, but as soon as they have adapted themselves to the changed conditions and the histologic lesions induced supply them with their necessary nourishment, then the parasites begin to multiply actively and the phase of incubation terminates. The article is accompanied by four colored plates.

33 *Three Cases of Recurring Pernicious Anemia. (Anémie pernicieuse à rechutes.) A. Gilbert and P. E. Weil.
34 *Angina Pectoris. (Angine de poitrine.) O. Josué.

33. Recurring Pernicious Anemia.—In the first of the three cases described the anemia developed in the course of chronic dyspeptic disturbances. The blood pressure improved with the digestion and became worse as the dyspeptic disturbances increased. In the second case jaundice ten years before was the only pathologic incident in the history. A tendency to jaundice was observed with the anemia, which possibly may be regarded as the result of a hemolytic icterus. The patient succumbed without any benefit from therapeutic measures, the anemia recurring in waves, yielding at first to arsenic. The last fatal exacerbation occurred after a period of great worry and overwork. In the third case, intense anemia was observed in a young bride after a fatiguing six months of travel. Multiple recurring hemorrhages kept up the anemia, but improvement followed an injection of 15 c.c. of diphtheria antitoxin. This seemed to control the hemorrhages, but the anemia continued a progressive course, being fatal in a few months. Such extensive hemorrhages as were observed in this case are very rare in pernicious anemia, and the remarkable way in which they were arrested by the antitoxin and later by an injection of simple defibrinated human blood is not the least interesting feature of this case. This serum treatment also gave temporary relief in the first case, an injection of 40 c.c. of rabbit serum. This serum treatment seems to be merely a symptomatic measure, but it has a promising palliative action and allows time to be gained.

34. Angina Pectoris.—Josué regards angina pectoris as exclusively a pain in the diseased aorta, and this aortic pain is always accompanied by a peculiar anguish. The lesions causing the pain are in the first part of the ascending aorta. The attack of pain is brought on by an emotion or an effort, and these causes are precisely those which increase the blood pressure. The diseased aorta is not painful under ordinary conditions, but the pain develops as the blood pressure rises, and it is favorably influenced by any measure that reduces arterial tension.

38. Drainage of Ventricle of Brain by Transplanted Blood Vessel.—Payr's long article reviews the anatomy and physiology of the lymph circulation in the brain. study of which has convinced him of the feasibility of treating hydrocephalus by draining the lateral ventricle, possibly into the longitudinal sinus, using some blood vessel to divert the fluid into the venous circulation or lymph spaces. He gives an illustrated description of the instruments he has devised for the purpose, and relates the history of three cases in which he has applied this technic as a last resort. Drainage of the ventricle was thus done five times on three individuals, but permanent benefit was not obtained in any case. The autopsy findings and the course of the cases confirm the practicability of the intervention and the mistakes to be avoided in future. The vision in one case had improved so much that hopes were entertained of permanent improvement, but the child succumbed to secondary infection of the ventricle. The operations were performed without mishap. A piece of the right saphenous vein. about 8 cm. long. was resected and implanted in the ventricle in one case, the patient being a girl of 9. In the second case a segment of the saphenous vein, resected on account of varices from a man of 52, was used for the ventricle drain in a child of 14 months. In the third case the temporal vein was cut and twisted around and the distal stump implanted in the ventricle. In conclusion Payr presents arguments to justify intervention along these lines. but warns that it is applicable only when the cerebrospinal fluid is limpid and sterile. The drain must be arranged with a valve action to prevent return of the fluid into the ventricle.

39. To Insure Asepsis in Operations on Intestines.—Wullstein ties a stout silk thread around the end of the bowel, in the groove made by the splanchnotribe on each side of the stretch to be resected. In tying the knot he slips over the silk thread three finer silk threads with which he is able to untie the knots and finally pull out the stout thread altogether. The fine threads can not be knotted, so he has each woven to form a loop, both ends woven together. The first loop is slipped on the middle of the stout thread and the second near it. The thread is then knotted and the third loop is slipped on one end before the final knot is tied. In order to distinguish the three loops he uses different colors, red, blue and yellow. After the abdominal wall is sutured in tiers he pulls on the red loop string. This unties the outer knot of the stout thread; pulling then on the blue loop unties the inner knot and the thread can then be drawn out completely by the yellow loop at its center. By this means the stout thread can be pulled out after the operation is entirely completed, as the threads can squeeze through the soft parts as they are drawn up from the depths. The presence of the loop threads does not interfere with the suturing, as traction on them does no harm but merely pulls the knots tighter, with the exception of the red loop in the outer knot; this must not be pulled on until ready to untie the knots. He has applied this same principle for removal of buried sutures. His article is illustrated.

40. Anatomic Behavior of Suprarenal Tissue.—By leaving a nourishing pedicle, it has been found possible to transplant a piece of suprarenal tissue in the kidney with apparent retention of function.

41. "Wound Scarlet Fever."—Kredel states that in the Hannover Hospital 28 cases of scarlet fever developed among the patients. In 12 the infection followed an extensive operation and in one a severe burn. The incubation was only three days in ten and from five to eight days in the others. He is convinced that the infection occurred in the operating room, and believes that antiseptic rather than aseptic measures might be preferable during prevalence of scarlet fever.

44. Progressive Necrosis of the Costal Cartilages.—Röpke reports four cases in which a localized abscess in a costal cartilage led to necrosis. The persistence of suppuration even after thorough evacuation of the focus in these cases confirms the necessity for extensive and early intervention to save the patients from many months of illness. The affection in his cases was secondary to typhoid, influenza with an abscess in the neck, fracture of the ribs or a suppurating wound in the vicinity. This property of the costal cartilage to take an active part in keeping up the suppurative process is due to the anatomic conditions and its peculiar mode of nourishment.

45. Ileocecal Tuberculosis.—Shiota summarizes the details of twenty-six typical cases in which the tuberculous process caused a tumor and stenosis. Treatment can be only surgical by resection. The results were good in a number of cases in which partial exclusion of the bowel was done. He compares the experiences of different clinics with ileocecal tuberculosis, the reports from nine showing an immediate mortality of 23.8 per cent. in 84 cases, but this mortality has dropped to 14 per cent. during recent years. In his own 11 cases of resection there was no immediate mortality nor persisting fistula, and all the patients are in good health from one to nearly five years since the operation, with the exception of one patient who succumbed in six months to debility.

47. Physiology of Artificially Induced Pneumothorax.—Shingu describes the experiences with artificially induced pneumothorax in 60 patients in the course of three years, and with numbers of animals, the communication issuing from Brauer's clinic at Marburg. The experimental research was undertaken principally to study the circulation of lymph in the normal and in the compressed lung, especially the circulation of inhaled particles of soot in the lymph. The lung was compressed by a pneumothorax or hydrothorax. The findings in nineteen rabbits are reported in detail, with colored plates in some instances. The most interesting finding in the experiments was, perhaps, the way in which the collapsed lung retained the soot particles, while the still normally functioning lung gradually cleared itself of the soot by way of the bronchi. This self-cleansing of the lung by the respiration is probably aided by the whirlpool movement of the inspired air and by the action of the ciliated epithelium moving the particles along toward the outlet. This self-cleansing function is probably an important means of getting rid of bacilli in the lungs. The collapse of the lung under the influence of a pneumothorax of course arrests this self-cleansing process, so far as it depends on the respiration. The experiences related confirm the old assumption that the tuberculous process develops more slowly the less active the lymph circulation in the part. It is still a question whether this is due to attenuation of the virulence of the bacilli under these circumstances or to an increase in the defensive properties. In some respects the conditions with an artificially induced pneumothorax are similar to those with Bier's hyperemic treatment, at least in so far as the lymph circulation is concerned. One advantage of the compression of the lung is that new relays of bacilli and dust particles can no longer be brought into the compressed lung, which thus escapes these deleterious influences. The lung is able to take care of the bacilli already in it by the self-cleansing functioning of the ciliated epithelium of the bronchi. This must have a favorable influence on the bronchitic process with its consequences, the cough, fever from proliferation of the bacilli, pains, etc. On the other hand, there is also a possibility that in existing bronchial catarrh, with especially tenacious secretion, the secretion may be retained and entail cheesy degeneration of the peripheral segments. The main factor in the cure of a tuberculous process by a pneumothorax is the checking of the proliferation of the tubercle bacilli from the compression—the lung tissue becomes more compact and the bacilli are unable to proliferate. The benefit from the pneumothorax in the clinic has been marked in many cases, and the pathologic findings in the three cases that came to autopsy showed unmistakable healing. The breathing lung works harder than usual, and there is danger that this excessive respiration may aspirate tubercle bacilli and other germs from the compressed lung into the breathing lung or from the air. It is therefore important that this lung doing extra work should have air as pure as possible to breathe. This pneumothorax treatment should not be attempted unless the lung that is to do the extra work is practically free from tuberculosis. The patient should keep as quiet as possible to keep the circulation of lymph at its lowest point and restrict aspiration of foreign bodies, dead or living, liable to induce inflammation. These conditions evidently cooperate in the benefit of the outdoor rest cure.

50. Treatment of Retrodisplacement of the Uterus.—Strassmann believes that this condition is more frequent than generally believed, and that it is favored by overfilling of the bladder, which pushes the fundus backward, and by overfilling of the rectum, which pushes the cervix forward and thus pivots the fundus backward. Another factor in backward displacement is any laceration of the cervix annulling its action as a solid tube. He urges the importance of examination four or five weeks after childbirth to detect and remedy incipient retroversion. He uses a ring pessary in certain cases, and thinks that about one-fifth can thus be cured or at least relieved from all disturbances. He warns that it is not wise to operate for retroversion resulting from inflammatory conditions in the adnexa, during the first year. The causal germs die off in the course of nine months, poisoned by their own waste products in the closed tubes. During the interim, conservative measures, local application of heat and hydrotherapy, may be applied. He does not approve of operating for retroflexion unless compelled by symptoms, but adds that a spontaneous abortion should always suggest the possibility of displacement of the uterus. If a retroflexed uterus has become corrected during a pregnancy, the wearing of a ring pessary may prevent recurrence. He warns in conclusion that the earlier a woman gets up after childbirth, the more puerperal are the genitalia, the wider the vagina, the less healed are the small lacerations which every parturient has, the larger is the uterus and the greater the burden on the floor of the pelvis. If the woman gets up early after delivery at home, she is sure to begin to work. For these and other reasons, he does not approve of allowing the parturient to get up early.

52. The Serum Test for Syphilis.—Sachs and Rondoni state that the conditions in regard to the dilution of the extract used for the test have a great influence on the findings. It seems probable that the complement-binding action is dependent on the size of the colloidal dissolved particles in the extract and not merely on its chemical properties alone.

53. Finger Plethysmograph.—Fleischer describes the experiences at Strauss' polyclinic at Berlin with the turgosphygmograph and with a new and simple apparatus he has devised to study the behavior of the pulse in the vessels in the finger. He gives an illustrated description of this "finger plethysmograph," with a number of tracings of the finger pulse in health and disease.

54. Phototherapy of Lupus.—Piorkowski relates a number of examples from his large experience to show the fine results that can be obtained in lupus from the use of various forms of light, selecting the special technic adapted for each individual case. The quartz lamp is found most effectual for small, solitary, superficial foci. It has such a powerful irritating action on the skin that the dosage must be applied cautiously. Roentgen therapy is best adapted for the preliminary treatment of suppurating surfaces. The results, both from the cosmetic and the functional point of view are not entirely satisfactory. Finsen treatment gives the most nearly perfect results, especially in the severer cases, and it is free from danger, he says, unless it is contraindicated by some organic affection.

56. Relations Between Human and Bovine Tuberculosis.—Fibiger is professor of pathologic anatomy at the University of Copenhagen, and Jensen is professor of general pathology at the veterinary and agricultural college and in this long monograph they give a detailed account of their experiences with transmission of tuberculosis to cattle from clinical cases. The cases are numbered as a continuation of their previous reports on the subject, and the material is tabulated for better oversight. In the 27 cases, tubercle bacilli virulent for cattle were found only in such cases as the *localization of the affection and the history* of the case rendered it probable that the tuberculosis in these patients had been derived from cattle. When the conditions indicated that the tuberculosis had been derived from a human source, the tubercle bacilli were not especially virulent for cattle. They do not accept the reverse conclusion, namely, that cases of human tuberculosis in which the bacilli are only slightly virulent for cattle are necessarily of human origin. Such an assumption is disproved by the cases in which the bovine type of bacilli could be derived from external lesions, while bacilli from the lungs and urinary passages were of the human type, as in a typical case reported in which the primary tuberculosis was a chronic verrucous affection of the skin in a man employed in slaughtering and dressing diseased cattle. Their experiences lead them to oppose any attempt to classify the types of tubercle bacilli according to their virulence for rabbits. Future research, they say, must be devoted to the study of the question whether tubercle bacilli in human and bovine tissues may not become transformed from one into a different type or types. This question is important from several standpoints, and is the key to the mutual relations between tuberculosis in man and in cattle. The monograph is continued through Nos. 42 to 45.

57. Differential Importance of Hemolytic Substances in Stomach Content.—Continuing their previous research, Grafe and Röhmer have now a record of 230 persons, with and without stomach affections, whose stomach content has been repeatedly tested for hemolytic properties. In 57 cases of certain cancer of the stomach the hemolysis was always pronounced, while it never was detected in the healthy content, and never under other conditions except when there was regurgitation of bile and pancreatic juice, which is especially liable to be encountered when there is considerable ptosis. It is necessary, therefore, to determine the presence of trypsin, and if it is found impossible to obtain the stomach content free from trypsin, the hemolytic property has no diagnostic value. The hemolysis is probably the work of some albuminoid substance, and it indicates an ulcerative process in the stomach. It is thus impossible to differentiate by this hemolytic test a large benign ulcerating ulcer from a small incipient cancer, so that negative findings are much more important than positive. Grafe and Röhmer reject the umbilicus as an unreliable basis for computing the amount of ptosis. A line connecting the highest points of the crests of the ilium is more reliable, and they accept as gastroptosis the cases in which the lower limit of the inflated stomach is at least two fingerbreadths below this line.

59. Disturbances of Conduction of Heart Impulse.—Rihl has studied a case of irregular heart action which he describes in detail and compares with others. Simultaneous registration of the arterial and venous pulse showed occasional dropped systoles of the ventricle with and without dropped auricular systoles. By pressure on the vagus during periods of regular heart action, it was possible to induce the dropping of ventricular systoles and arrest of the contractions of the auricle. During the ventricular pause from the pressure on the vagus, the ventricles contracted independently of the work of the auricles; these contractions were evidently automatic.

61. Significance of Abnormally High Temperature.—Rolly and Meltzer report extensive experimental researches which demonstrate, they think, that a febrile temperature is liable to have a favorable action in bacterial infections, and that phagocytosis is promoted, as also the production of antibodies. The rising temperature with infectious processes may thus be regarded as a means of defense, arousing the cells to increased activity, so that the specific antibodies are produced earlier and in increased amounts. There did not seem to be any permanent injury to the animals from the prolonged febrile temperature, but there were certain transient disturbances such as loss of weight and lower hemoglobin percentage.

66. Determination of the Viscosity of the Blood.—Bachmann advises determining the viscosity of the blood in connection with hemoglobin, the experiences showing that the hemoglobin divided by the viscosity gives a quotient which is nearly constant in health, but which varies widely in different diseases. In pneumonia the viscosity is increased; in typhoid it is reduced, as also in chronic interstitial nephritis. In thrombosis the viscosity may range from average to maximal figures. The higher the viscosity the graver the prognosis. In epidemic meningitis the viscosity is always pronounced.

73. Hemorrhage in the Adipose Capsule of the Kidney.—A man of 50 with a tendency to gout suddenly developed intense pain in the right kidney region with collapse, transient anuria and paresis of the intestines. The temperature rose, there was hemorrhagic suffusion of the skin in the region, a resistance could be palpated, and the patient grew constantly weaker, but with no signs of anemia and with no abnormal urine findings. Operation revealed hemorrhage in the adipose capsule and around the kidney. The blood-soaked tissue was removed, but the apparently intact kidney was not disturbed. A complicating pneumonia and the persistence of symptoms soon compelled nephrectomy which the patient did not survive. Autopsy revealed further a septic tumor in the spleen. Joseph remarks in conclusion that the circumstances in this and the two similar cases on record indicate that the patients might have been saved by earlier removal of the focus in these cases of "apoplexy of the bed of the kidney."

75. Hernia of the Bladder.—Eggenberger adds 110 cases to the previous statistics of 182 collected by Brunner in 1896. The list includes 5 from his own experience. He summarizes this later series, classifying the cases and discussing the treatment. In operating on a manifest cystocele the bladder is never injured and the disturbances subside after its reduction. The outlook is not so good with the latent bladder hernia discovered as a complication at a herniotomy, as the bladder is liable to injury in this case. The conditions are still worse when the participation of the bladder in the hernia is not discovered at the time of the operation. The mortality in this case still amounts to 30 or 40 per cent., and tedious fistulas are frequently left.

76. Clamping of Large Vessels Near Heart.—Research on this subject was undertaken at Trendelenburg's clinic to throw light on the conditions in pulmonary embolism and the best means of operative intervention. After simultaneous constriction of the pulmonary artery and the aorta in rabbits, the heart and brain seem to suffer most, but the former is more resistant and adapts itself better to the changed conditions. It finally yields to their injurious influence, the overfilling of the organ and the impossibility of emptying it, the lack of fresh nourishing blood in its arteries and the central irritation of the vagus center, all combining to arrest the heart action in time. The heart can stand this for six minutes, however, and the animals apparently tolerated without injury simultaneous constriction of the aorta and pulmonary artery for the space of one minute. This gives ample time in operating on man to take the thrombi out of the branches of the pulmonary artery, or, if not, the constriction could be removed and the wound in the artery closed with a special clamp. Then, after the circulation has been proceeding normally for a few minutes, the constriction could be applied anew. It is unnecessary, theoretically, to apply artificial respiration while the pulmonary artery is occluded, as no blood can then pass through it to be oxidated in the lungs. It is all the more necessary, however, after the constriction has been removed and the circulation through the lungs starts up once more. Experiments in which the two arteries were constricted separately produced the same results as when the two were constricted at the same time. One rabbit survived after the circulation in the pulmonary artery had been shut off for one minute, while an operation as for pulmonary embolism was being done. The animal was lively at once as soon as it recovered from the ether. Other experiments with occlusion of the large veins showed that the coronary and pulmonary circulation was maintained at least for a time. Puncture of the left ventricle during this experiment showed pronounced arterial blood and in the right ventricle dark venous blood. The heart tolerates constriction of the large veins better than of the large arteries. The heart resumed its functioning when the vena cava had been constricted for nine minutes, but irreparable disturbances had occurred in the brain.

the corneal reflex being permanently abolished. The rabbits were able to tolerate without apparent injury constriction of the large veins for 3¾ minutes. If the venæ cavæ are tied off to arrest hemorrhage in the clinic, brain complications can be avoided by releasing the pressure from time to time to allow the blood to circulate freely once more through the brain, even at the loss of a little more blood in hemorrhage. Rabbits were used for all the tests reported and the arteries were constricted with yarn dipped in oil. The artery is readily lifted by the piece of yarn passed underneath, and crossing the ends of the yarn constricts the lumen completely. The veins were occluded with small Dieffenbach clamps with the sharp edges filed off.

83. **Symptomatic Treatment of Tuberculosis.**—Senator remarks that symptomatic treatment of all affections is too much neglected. Besides the causal and the specific measures, the symptomatic should be used more systematically than is frequently the case, especially in tuberculosis. He takes up the various symptoms in turn and discusses the best measures for their relief. In hemoptysis the most complete repose is imperative—avoidance of physical and mental exertion of any kind. Severe coughing is injurious and should be prevented as it never expels all the blood, while pure blood in the air passages is readily absorbed without harm. Sedatives should therefore be given to control the cough; even morphin may be useful. It has the further advantage that it tranquilizes the patient, who is usually frightened and excited by the hemoptysis. Digitalis may also prove useful in case the heart is acting too stormily. Application of cold to the chest may aid by reflex action in inducing contraction of the blood vessels, but if it causes the patient to feel chilly it is best to discontinue it. He has never witnessed much benefit from astringents, except possibly lead acetate, which seems to increase the coagulability or viscosity of the blood. Inhalation of astringents, to do any good, would have to be so powerful that it would keep the parts from the needed repose. Ergot, hydrastis and similar drugs, useful to stimulate the sound uterine muscle to contract, are liable to do harm here as the bleeding vessel is diseased and thus not able to respond to the stimulus. If the sound parts around contract, the hemorrhage may be increased. Gelatin is liable to do good service. Although it is more effectual subcutaneously injected, he gives it also by the mouth and in enemas, regarding it as a valuable means of supplying nourishment, in addition to its hemostatic action. If the hemorrhage remains profuse, he supplements these measures by applying a tourniquet to the arms and legs to shut off the circulation in these parts. This must be done cautiously, not allowing too much congestion in the limbs, and with care to release the dammed circulation from only one limb at a time, to avoid too much flooding of the lungs when the general circulation is restored. If further measures are needed, the suprarenal preparations might be tried, although their action in contracting the blood vessels is of little use—they seem, however, to have some further influence on the blood itself. Lead acetate might be alternated with them. Slight fever may be controlled by repose and frequent, easily digested meals. If the fever keeps high, he paints the skin with 1 or 2 gm. (15 or 30 grains) of guaiacol, covering the region afterward with rubber tissue—the temperature generally drops in less than an hour afterward. This is such a powerful measure that he warns not to use more than 0.5 or 0.75 gm. (7½ or 10 grains) for very sensitive patients. The salicylates are liable to injure the stomach and increase sweating. To prevent night sweats no warm food or drink should be taken in the evening, and the trunk should be gently rubbed with cool vinegar water or fluid formalin soap. Atropin stands at the head of internal remedies, if such are indispensable, but it should be given with great caution. Dietetic treatment of the diarrhea with warm packs of the trunk and, possibly, warm Ems Kesselbrunnen water, mornings, fasting, and again several hours after dinner, generally keep the diarrhea under control unless the intestinal lesions are very extensive. If drugs are needed, he prefers an infusion of a mild vegetable drug.

85. **Artificially Induced Pneumothorax in Tuberculosis of the Lung.**—Forlanini advanced the theory of this procedure in 1882 and in 1894 published clinical experiences with it. He here reviews the whole subject and its history to date, with thirteen illustrations of the technic which he has found most effectual, apparatus, etc. The method is indicated, he says, for the uncomplicated cases of unilateral pulmonary tuberculosis with a slow or subacute course and with free pleura, without regard to the extent or degree of the lesion. In such cases the pneumothorax treatment is simple, comparatively short, and leads to an effectual cure. He adds that it may be indicated in the acute unilateral cases when other measures fail or are impracticable for any reason. The treatment is also indicated as above even in the presence of pleural adhesions if they can be broken up with the pneumothorax, but in such cases the method is harder to apply and the course of treatment much longer. He admits, further, that the pneumothorax treatment is applicable to cases of bilateral but not acute phthisis. The article is to be continued.

87. **Ulcerative Processes in the Mouth.**—Ritter relates a number of instances of severe ulcerative processes with necrosis in the mouth. Those originating in irritation from a tooth or other accidental cause can generally be arrested by energetic measures, but the prognosis is more serious of those on a basis of tuberculosis, leukemia or other constitutional taint. One of his patients was a woman of 35, who developed ankylosis of the jaws three weeks after extraction of a wisdom tooth. An ulcerative process followed, rebellious to antisyphilitic and other treatment, and which soon assumed fatal malignant features. In another case a small boy developed an ulcerative stomatitis in consequence of prolonged treatment with phosphorus on account of rachitis and debility. The necrosis was so pronounced that there was no resource except curetting without regard to preservation of the dental germs for the permanent teeth. Ritter refers in conclusion to the ulcerative processes liable to follow injection of cocain, warning that prolonged anemia of any part is liable to be followed by the death of the part and necrosis, consequently the dose of cocain should be small, and the parts not allowed to be unduly distended. The action on the heart must also be cautiously watched. Palpitation and a tendency to syncope are liable to be observed in anemic individuals. In one case edema of the sublingual glands was observed after removal of an incisor under cocain-adrenalin. The glands suppurated and opened outward.

96 *Importance of *Proteolytic* Leucocyte Ferment in Pathologic Physiology: Absorption, Autolysis, Fever, and Changes in the Coagulating Property of the Blood. G. Jochmann.

96. **Importance of Proteolytic Leucocyte Ferment for Pathologic Physiology.**—Jochmann has succeeded in isolating the proteolytic ferment of the polynuclear neutrophile leucocytes and has been studying its action in various pathologic conditions. His research indicates that this ferment plays a considerable part in the autolysis of most of the organs and that its power of digesting albumin facilitates the process of absorption, while the liberation of the ferment in large amounts has an undoubted action in raising the temperature, and may be responsible for the aseptic fever observed under various conditions, such as the slight fever after a normal childbirth, the fever in myelogenous leukemia, after Roentgen exposures, and after injection of silver salts. The ferment also seems to reduce the coagulating power of the blood at first, but in large doses it has the opposite effect.

Wiener klinische Wochenschrift.

November 5, XXI, No. 45, pp. 1545-1580.

97 *Advantages of Institutional Care of Childbirth. (Geburtshilfe in Anstalten und ausserhalb derselben.) F. Schauta.
98 Experimental Transmissible Tumors. (Zur Kenntnis der übertragbaren tierischen Tumoren.) K. Landsteiner.
99 *Diarrhea from Gastric Achylia in Children. A. F. Hecht.
100 *Microchemical Test for Mucus in Stools. (Neuer mikrochemischer Schleimnachweis im Stuhl.) Id.
101 Poisoning from Fishberries Used as Abortifacient. (Zur Kasuistik der durch Kockelskörner 'hervorgerufenen Vergiftungen.) E. Homa.
102 Umbilical Hernias. (Nabelhernien.) A. Fraenkel.

97. **Obstetrics in and outside of Lying-in Hospitals.**—Schauta urges the more general preaching of the gospel that when a woman is facing a childbirth she should avail herself of the superior advantages of institutional care as a matter of course. To the sentimental objection that in this hour of stress she wants to be in the bosom of her family, he replies that any laparotomy is as much an hour of stress as a childbirth, and yet that no one thinks of advising a laparotomy to be done in the home except under extraordinarily favorable conditions. Every obstetrician knows how much more difficult his task is rendered by the environment of the ordinary private house, and how he is frequently unable under the circumstances to do what his reason tells him should be done for the ultimate welfare of mother and child. The family physician or obstetrician should still have charge of the case, as in the home, only he should have all the resources of the modern well-equipped lying-in hospital to back him. He should be able to determine during the last half of gestation whether the delivery is liable to be pathologic or not, and if so, the woman should be advised to go to some institution. Among the arguments he cites to sustain this contention is the fact that in Mecklenburg, 1887-1897, two-thirds of the fatalities from puerperal infection were in women who had required some obstetric operation. Other statistics also teach the same lesson, namely, that the mortality from puerperal infection outside of institutions is still as high, or even higher, than in the preaseptic days, while in the maternities the mortality is less than a thirtieth of what it used to be.

99. **Gastric Achylia in Children.**—Hecht's experience indicates that every chronic diarrhea is suspicious of achylia, and he urges that the gastric secretions should be investigated in every such case. In a recent case of the kind, a girl of 9 had long suffered from chronic diarrhea, and during weeks of observation no hydrochloric acid and no lab ferment, and scarcely any splitting of fat, were discovered in the stomach, while there was very little to show the action of pepsin. There was a suspicion of tuberculosis also, but the case is a typical example of chronic diarrhea resulting from gastric achylia. It is probable, he adds, that such cases will be found to be more numerous than suspected at present, if the gastric secretion is systematically investigated in patients with a chronic tendency to diarrhea.

100. **Microchemical Test for Mucus in Stools.**—Hecht adds to a scrap of stool a drop of a mixture of equal parts of a 2 per cent. solution of brilliant green with a 1 per cent. solution of neutral red, diluted. The mucus stains red, while the rest of the stool is green, except the nuclei and membranes of cells.

104 Injury of Hepatic Duct During a Cystectomy. (Verletzung des Ductus hepaticus bei der Cystektomie.) W. Volkmar.
105 Modified Cannula for Transfusion according to Crile. (Eine modifizierte Crile'sche Transfusionskanüle,) L. Buerger.

103. **Osteoplastic Restoration after Resection of Jaw.**—Rydygier gives an illustration of the method of using a strip cut from the front of the clavicle to fill the gap left by resection of the under jaw. The strip of bone is wrapped in a corresponding pedunculated skin flap in which it is allowed to heal before being transplanted. The one case in which he had occasion to apply this technic amply confirmed its practicability and successful results.

Zentralblatt für Gynäkologie, Leipsic.

106 Polypous Ovarian Cystoma. (Fall von polypösem Eierstockskystom.) A. Grasmueck.
107 *Placental Theory of Etiology of Eclampsia. J. Hofbauer.
108 Attempt to Follow Sellheim's Technic for Extraperitoneal Cesarean Section. (Versuch eines extraperitonealen Kaiserschnittes nach Sellheim.) Uthmöller.
109 Operation by Rehn-Delorme Technic for Prolapse of Rectum. (Operation eines Mastdarmprolapses nach Rehn-Delorme.) Id.

107. **Placental Theory of Eclampsia.**—Hofbauer reviews the arguments for and against the assumption that ferments from the placenta are liable to induce partial intravital autolysis of the liver. The toxins resulting from the autolytic process and also from the defective functioning of the liver are responsible for the development of the eclampsia. The testimony is overwhelmingly in favor of this assumption, he says. It should not be called a theory, he adds, as it is a complex of interdependent facts which have each been demonstrated with the exception of the ferments in the placenta; these as yet are known only by the results of their action.

Gazzetta degli Ospedali e delle Cliniche, Milan.

November 1, XXIX, No. 131, pp. 1405-1420.

110 *Temporary Hemostasis During Removal of Kidney Stones. (Emostasi temporanea nelle nefrolitotomie.) G. Caponetto.
111 *Neutral Potassium Oxalate for Treatment of Phlegmons. Adenitis and White Swelling. (Dell'Ossalato neutro di potassa nella cura del flemmone, della adenite e della flemmasia alba dolens.) G. Cavazzani.
112 Sea Bathing in Treatment of Certain Tuberculous Affections. (Cura di alcuni processi tubercolari merce i bagni marini.) R. Passini.
113 *Suddenly Fatal Electric Accidents. (Morte improvvisa da scarica elettrica.) A. Tonello and L. Confalonieri.
114 *Study of Abdominal Colic. (Sulle coliche addominali con speciale riguardo al dolore epigastrico.) M. Lodi.

110. **Temporary Hemostasis During Operations on the Kidneys.**—Caponetto uses an elastic cord or very fine rubber drain, passing it doubled through a metal tube, curving a little at the outer end from which the loop of the elastic cord projects. The rubber cord is passed around the pedicle of the kidney and by pulling on the outer ends of the cord and seizing them with a clamp, the desired amount of compression on the pedicle of the kidney can be automatically maintained without the slightest injury of the tissues. He has noticed that the suprarenal preparations seem to exert a more energetic action on the renal than on other blood vessels.

111. **Potassium Oxalate for Acute Suppurations.**—Cavazzani reported in 1897 his favorable results in treatment of phlegmons, suppurating glands and phlegmasia alba dolens with neutral potassium oxalate injected in fractioned doses in a 2 per cent. solution. He here reports that his later experience has confirmed his previous announcements. This drug seems to possess stimulating, opsonic and colloidal properties, he says, and it has proved particularly useful in cases of phlegmasia alba dolens. He gives the details of his last series of nine cases; recovery was complete in from four to forty-two days, with an average of less than twenty. The injections were repeated once, at an interval of five or six days. From 3 to 4 c.c. of the 2 per cent. solution of the neutral potassium oxalate are injected, fractioned, at ten or fifteen different points around the swollen lesion, the needle being introduced deep into the subcutaneous connective tissue. A third application is rarely required.

113. **Electric Accidents.**—In Tonello's case, a man of 37 succumbed suddenly to the passage of a current of 165 volts through his body as he held a 16 candle power lamp in his hand. The lesions found at autopsy indicated that death was the result of paralysis of the heart and respiration from the weak electric current acting on an individual with lesions in pleura, thyroid and pericardium reducing the resisting powers, with the additional factors of extreme heat, sweating and much lime dust in the air. The pathologic anatomic conditions caused by the electric discharge seemed to be identical with those encountered in death from asphyxia.

114. **Study of Abdominal Pain.**—Lodi analyzes the various forms of abdominal colic, especially pain in the epigastrium, as a means of differentiating herpes zoster, rupture of the muscles, phlegmon of the subperitoneal tissue, acute peritonitis, intestinal affections, affections of the pancreas, intestines, stomach and liver, cysts in the mesentery, kidney stone, diaphragmatic pleurisy and aneurism of the aorta. besides the pain accompanying diffuse or constitutional disorders, such as hysteria, tabes, lead poisoning, diabetes, etc., and abdominal pain as a reflex phenomenon.

118 Clinical Arguments in Favor of Assumption of "Cerebellar Neurasthenia?" (Nevrosi e forme organiche.) G. L. Lucangeli.

115. **Typhoid Localized in the Kidneys.**—In the first of the two cases described, a young woman, apparently convalescing from pleurisy, developed severe kidney symptoms, which bacteriologic examination showed were due to a typhoid septicemia localizing almost solely in the kidneys. The second patient was a boy of 14, with a focus of bronchopneumonia and hematuria with numerous tube casts and blood corpuscles. The diplococcus was cultivated from the sputum, but there was nothing to explain the urinary findings until the remarkably low number of leucocytes suggested the possibility of typhoid. The fever was intermittent in character, and there were no symptoms on the part of the abdomen, no typhoid bacilli in the stools, and the specific gravity of the urine was normal, as also its amount. However, typhoid bacilli were found in the urine and the agglutination test gave positive findings. The syndrome was never very serious and the child recovered.

Original Articles

THE DURATION OF LIFE AFTER EXTENSIVE HEMORRHAGE OF THE BRAIN.*

WILLIAM G. SPILLER, M.D.

Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania.

PHILADELPHIA.

My attention has been called recently to a diagnosis of apoplexy in a case in which life terminated in about five or ten minutes after a severe attack began. The person, a woman, had been in good health previously, was nearly 70 years of age, and after retiring was heard to groan. She was found within a few minutes with her head hanging over a bath-tub and her face much congested. A physician, called at once, pronounced her dead and gave apoplexy as the cause of death.

My experience has not justified a diagnosis of apoplexy in cases in which life has been terminated so quickly. I have taken thirteen specimens from my collection of pathologic conditions, in which extensive hemorrhage of the brain was found at necropsy. Many of these were from cases in my service at different hospitals; others were from cases in the service of Dr. Mills. In all instances life had been prolonged at least hours after the onset of the apoplexy, even when the hemorrhage was very extensive, had broken into the ventricles, and filled all the ventricles, even the fourth. In two cases of this kind (1 and 2) life was prolonged several hours; in one about five hours, in the other eighteen to twenty hours.

As a rule extensive rupture into the lateral ventricles is followed by more rapid death than when the ventricles escape, but a moderate hemorrhagic exudate into the ventricles is not necessarily rapidly fatal. In nine cases (3, 4, 5, 6, 7, 8, 9, 10 and 11) the lateral ventricles were implicated. In Case 3 death occurred after three days; in Case 4 after eleven days; in Case 5 after at least five days; in Case 6 after at least twenty-four hours; in Case 7 after five or six days; in Case 8 after about five days; in Case 9 after about a day and a half; in Case 10 after sixteen days; in Case 11 after about two days.

Case 10 is remarkable in that the hemorrhage was very extensive in the left cerebral hemisphere and extended into both lateral ventricles, and yet the patient lived sixteen days.

In Cases 12 and 13 the ventricles were not implicated; in Case 12 life persisted a little over six days; in Case 13 almost two months.

It seems to be held by some that life must be terminated within a few days if the hemorrhage has destroyed a large part of one cerebral hemisphere, but Case 13 shows this is not necessarily so. In this case, in which life persisted almost two months, the clot was found partly encapsulated and measured 7 x 2.5 cm. It destroyed the lenticular nucleus, a large part of the posterior limb of the internal capsule and extended to the island of Reil. It is truly remarkable that the brain may be so severely injured without a speedy termination of life.

The cases, briefly presented, are as follows:

CASE 1 (No. 308).—*History.*—W. E. L., aged 52, became hemiplegic on the left side after an apoplectic attack November, 1905, and was unconscious twenty-four hours. He became able to walk later, and on different dates had a few convulsions. On Nov. 20, 1905, shortly after noon, he fell to the floor, and was put to bed perfectly conscious, but very gradually he began to lose consciousness, and in about an hour after the fall he was entirely unconscious. He then had a severe convulsion and died about 5 p. m. the same day. He lived about five hours after the beginning of the apoplectic stroke.

Autopsy.—A large hemorrhage had destroyed the right lenticular and caudate nuclei, and had filled all the ventricles, even the fourth, and had extended to the base of the brain. The hemorrhage was chiefly ventral to the lenticular nucleus, but extended into the front part of this structure, and had broken into the anterior part of the right lateral ventricle. Much blood was found over the pons and medulla oblongata.

CASE 2 (No. 370).—*History.*—John E., aged 26, was admitted to the hospital Sept. 15, 1906, and died Nov. 17, 1906. About five weeks before admission he took a large dose of quinin; he then became very drowsy and was unconscious for three days. When he recovered consciousness he was paralyzed on the left side. He was able to walk about a week later. The notes state that "yesterday" in the afternoon he had severe repeated convulsions, lasting until his death. His pulse reached 160; sweating was profuse; he vomited, and died the following day at 10:30 a. m. He, therefore, lived about eighteen to twenty hours, or at least from the afternoon of one day to 10:35 o'clock of the next day.

Autopsy.—The hemorrhage filled all the ventricles completely, destroyed the greater part of the right cerebral hemisphere, including the region of the lenticular nucleus and the right occipital lobe.

CASE 3 (No. 357).—*History.*—Charles S. was brought into the hospital Oct. 2, 1906, unconscious, and did not regain consciousness before his death, on Oct. 5, 1906. He was paralyzed on the right side. He lived at least three days.

Autopsy.—A hemorrhage was found measuring 2x7 cm. It destroyed the left lenticular nucleus, part of the posterior limb of the internal capsule, and extended almost from the posterior horn of the lateral ventricle to the anterior horn, and ruptured into the latter, distending it with a recent clot.

CASE 4 (No. 286).—*History.*—William U., aged 72, had had diabetes many years. He retired at his usual time the night before admission to the hospital, and was found at noon, March 15, 1905, lying at the side of the bed. When seen by his physician at 12:30 p. m. he was semi-conscious and paralyzed in the left upper and lower limbs. His speech was mumbling. He was brought to the hospital March 15 and died March 26. He, therefore, lived eleven days after the stroke.

---

*From the Department of Neurology and the Laboratory of Neuropathology in the University of Pennsylvania.

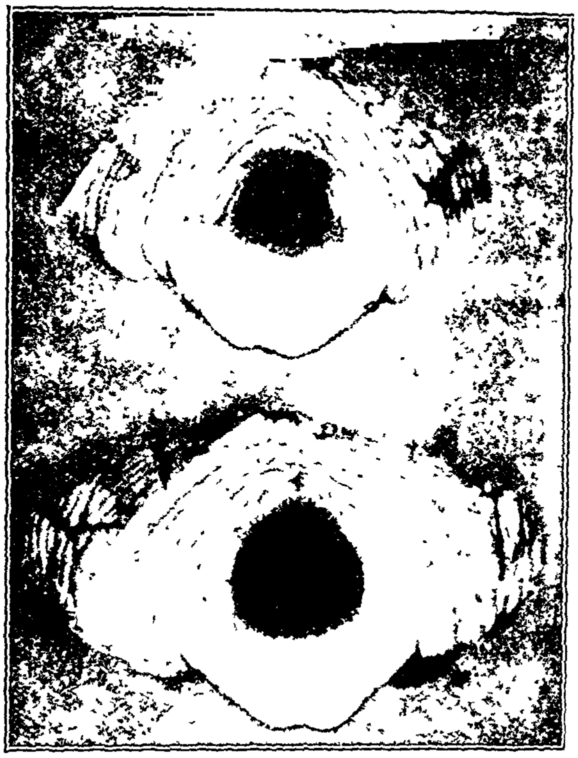
Autopsy.—A large hemorrhage was in the right internal capsule, optic thalamus and lenticular nucleus and a clot filled the center and part of anterior horn of lateral ventricle.

Case 5 (No. 144).—*History.*—Annie S., aged 35, was admitted to the hospital Nov. 5, 1897, in a semi-conscious condition, with a history of acute alcoholism of three weeks' duration. Some twitching of the facial muscles was noticed on the fifth day. The date of death is *not given, but the* statements show that she lived at least five days.

Autopsy.—A large hemorrhage was found in the left lateral ventricle, not extending into the posterior horn. The inner surface of the lenticular nucleus and the anterior portion of the optic thalamus were disorganized. The hemorrhage was evidently recent, the blood being dark colored and soft.

Case 6 (No. 50).—*History.*—James L., aged 76, was admitted to the hospital Nov. 5, 1897, *paralyzed on* the right side and deeply *stuporous. In the morning* of the same day *he had fallen* unconscious while walking. The day following admission he was more conscious and noticed those about him, but he gradually became more stuporous until his death. The date of death is not given in the notes, but the statements show that the patient lived at least until the next day.

Autopsy.—A large amount of clotted blood was found in the left lateral ventricle. Hemorrhage filled both ventricles, and on the left side had invaded the thalamus, the posterior portion of the lenticular nucleus, the internal capsule, and the adjoining part of the occipital lobe.



Photographs of sections made through the pons in Case 2, in which the greater part of the right cerebral hemisphere was destroyed and all the ventricles were filled with blood. The great distention of the fourth ventricle by the blood clot is shown. The surrounding tissue was stained from the blood. The patient lived eighteen to twenty hours after the attack began. (Photographs by Dr. Alfred Reginald Allen.)

Case 7 (No. 318).—*History.*—James W., aged 37, became paralyzed on the right side during the night of July 4, 1905. He improved greatly. He fell on the evening of Dec. 12, 1905, and became stuporous, had conjugate deviation of the head and eyes to the right, and paralysis of the face and limbs on the left side. He improved considerably. On December 23 it is stated that he had been more stuporous for a few days and his pulse was weaker. He was still more stuporous on December 24, did *not* change his position in bed, and the pulse was weak and rapid. The pulse was hardly perceptible on December 25, and the man was very weak. He lived five or six days in a very critical condition.

Autopsy.—A hemorrhage, 2.5x3 cm., was found in the occipital lobe. It extended into the lateral ventricle.

Case 8 (No. 336).—*History.*—Charles H., aged 80, was admitted to the hospital Oct. 28, 1899, and died March 11, 1906. He was brought from the out wards March 6, 1906, in an *unconscious condition. The* breathing was stertorous. The head and eyes were *turned to* the left. The right upper and *lower limbs and the right side of the* face were paralyzed. He died March 11, 1906, at 10:40 a. m. He lived about five days.

Autopsy.—The hemorrhage destroyed the posterior part of the left optic thalamus and of the posterior limb of the internal capsule and lenticular nucleus, and filled the descending horn of the left lateral ventricle.

Case 9 (No. 273).—*History.*—Harriet J., aged 44, fell to the floor and became unconscious on Jan. 14, 1905, at 9 a. m. When she was brought to the hospital the same day she was stuporous but could be aroused, and was paralyzed on the right side. Speech was almost unintelligible. From 11 a. m January 15 she was almost continually in convulsions until death. Lumbar puncture was *performed* at 5 p. m., and the patient died that evening. She lived about a day and a half.

Autopsy.—A large hemorrhage 6.5x4 cm., of recent development, was found in the left lenticular nucleus, extending into the internal capsule, and at the anterior end of the left ventricle had broken into the ventricle. Hemorrhage was found in both lateral ventricles, but mostly in the left.

Case 10 (No. 429).—*History.*—Ernest W. was admitted to the hospital Jan. 25, 1908, and died Feb. 10, 1908. While *working about the hospital on January* 25 he suddenly fell and became paralyzed on the right side in face and limbs He was *stuporous but could* be partly aroused. Loud commands were not heeded. He had dysphagia, aphonia and enuresis. *He showed no improvement* on February 2. The pulse was 105 and feeble. He lived sixteen days, a remarkably long time in consideration of the extensive hemorrhage.

Autopsy.—A hemorrhage occupied a large part of the posterior half of the left cerebral hemisphere, and both lateral ventricles contained blood. The clot within the hemisphere measured 5x5.5 cm. and at one level 5.5x6.5 cm.

Case 11 (No. 230).—*History.*—Miss H., aged 50, fell on the evening of April 19, 1904, became completely unconscious, and seemed to be completely paralyzed. On April 21 the pulse was weak and respiration stertorous. She died that afternoon. Life was prolonged almost two days.

Autopsy.—A large hemorrhage was found filling the whole of the left lateral ventricle but not extending into the right ventricle. The substance of the brain was implicated in the lesion only near the anterior part of the left lateral ventricle.

Case 12 (No. 241).—*History.*—Gottlieb R., aged 77, was admitted to the hospital July 19, 1904. The attack occurred suddenly during the night before admission, and the patient was found lying on the floor unconscious. Respiration was of Cheyne-Stokes type. The paralysis was complete on the left side The pulse was rapid. The patient was *partly* conscious on July 20, and improved somewhat later until July 24, but died July 25. He lived a little over six days.

Autopsy.—A hemorrhage measuring 4x5 cm. had destroyed the greater part of the right lenticular nucleus, the posterior part of the posterior limb of the right internal capsule, and extended beyond the *posterior portion* of the optic thalamus.

Case 13 (No. 348).—*History.*—Hesse, aged 40, was admitted *into the hospital in an* unconscious condition March 20, 1906. No history was obtainable. The patient had been found *in a stable. He had conjugate* deviation of the head and eyes *to the left and paralysis of* the right upper and lower limbs. *He was stuporous and* did not speak at any time. No marked improvement occurred during his *long* stay in the hospital. An operation was performed and a subdural hemorrhage over the left temporal region of the brain was removed. He died May 18, 1906, two weeks after the operation. This case was noteworthy because of the long duration of the hemorrhage.

Autopsy.—A large blood clot was found in the left cerebral hemisphere, measuring 7 x 2.5 cm. It had destroyed the lenticular nucleus, a large part of the posterior limb of the internal capsule, and extended to the island of Reil. The clot appeared of long duration and was *partly* encapsulated.

4409 Pine Street.

THE SPHENOIDAL SINUS.

A STUDY BASED ON THE EXAMINATION OF EIGHTY-FIVE SPECIMENS.*

JAMES A. GIBSON, M.D.
Professor of Anatomy, Medical Department, University of Buffalo.
BUFFALO.

In presenting this paper, I may say that I was led to take up this subject for several reasons, one of which was the difficulty I had in obtaining definite details concerning this cavity, another was that I believe its importance is underestimated by the majority of practitioners. I would bespeak careful consideration for this sinus, occupying as it does a central position in the cranial cavity, being on the one hand in close relationship with the most important and delicate parts of the encephalon, and on the other by its communication through the nasal cavity with things external.

It is much more difficult of approach than either of the other bony sinuses and presents decidedly more complicated relations. Compared with the ample investigation the maxillary and frontal sinuses have received, the sphenoidal sinus has been somewhat neglected. Much work must yet be done in this connection, particularly in regard to the lymphatics of the sinuses. Poirier and Cuneo say, "Our knowledge of the lymphatics of the mucous membrane which lines the cells and sinuses of the nasal fossæ is still imperfect. The small degree of development which these cavities present in the infant (the usual subject for experimentally injecting the lymphatics) renders the study of these lymphatics somewhat difficult. On account of the practical interest which is attached to this question from the standpoint of the pathogeny of certain cerebral lesions, consecutive to nasal infection, we think it advisable that further researches should be undertaken on this particular point." A study of even a very limited number of sphenoids will amply justify the above quotation. The number of important structures surrounding the sinus on almost all sides is great, in many cases the bony separation is of the thinnest and most delicate character and suggests great possibilities of cerebral involvement due either to trauma or infection.

Some of the important structures in relation with the sphenoidal sinus are, anteriorly, the ethmoid bone, containing the anterior and posterior ethmoid cells, in front of this the frontal and nasal bones, by means of which, as has been recorded,[1] the force of a blow received on the forehead has been transmitted as far back as the body of the sphenoid, resulting in the laceration of the internal carotid artery with fatal hemorrhage. The optic commissure and nerves are placed above and on either side of this sinus. The cavernous sinus and ophthalmic veins skirt the lateral wall of the sinus, as does also the internal carotid artery. Partly above and partly behind is the pons, with a large and important set of veins ramifying over the posterior wall and basilar process. The second division of the fifth nerve lies close enough to it to be occasionally encroached on by the sinus, as mentioned in one of my cases. The maxillary sinus may be separated from the sphenoid sinus by an exceedingly thin plate of bone and may, occasionally, communicate with it. Below the sinus is placed the vomer, strengthening the floor and adding to its thickness, and also incidentally to the difficulty of approaching it from this direction; the naso-palatine nerves intervene between the vomer and the sphenoid.

The data contained in this paper are the result of an examination of eighty-five sphenoidal sinuses. Obviously it was impossible to obtain perfect specimens in many cases. Some of the dry ones have been injured in the cutting, and some of the dissection specimens are partial. For these reasons I have included in this series material from which complete observations could not be made. This series will be continued at a later date.

The exact age could not be obtained in many cases and has frequently been estimated. The term "dry" signifies that all the soft tissues have been removed, while the term "dissecting-room" is applied to those specimens used just as they come from the dissecting table without a further removal of the soft structures. This would cause a very slight difference in measurements. Sagittal sections were made as nearly in the median line as possible, while coronal sections were cut through the middle of the pituitary fossa.

In laying down rules for the measurements it was found impracticable to select certain anatomic points as universal standards for measuring. The position of the sinus varies greatly, therefore no two points will give a universal maximum or minimum measurement. I have, therefore, taken the maximum measurement in the antero-posterior, transverse and vertical directions. This same difficulty is met with in obtaining the thickness of the walls of the sinus; I have taken the thinnest point as my standard, except where there is a very marked difference, as is usually seen in the posterior wall; here I have frequently given the maximum and minimum thickness.

These observations have been made with the following points in view:

1. The collection of definite data regarding the position, size and extent of the sinus.
2. The average thickness of its walls.
3. The relationship in size, if any, between the frontal, sphenoidal and maxillary sinuses.
4. The relationship, if any, between a large posterior nares and a small sphenoidal sinus, or the reverse.
5. The establishment of certain averages between anatomical points, obtainable in the living subject, which might be of assistance to the surgeon.
6. The recording of abnormalities and their possible influence on surrounding parts.

In this series there are males, 77; females, 7; unknown, 1. Total, 85.

The preponderance of male specimens renders any comparison under the head of sex of no value. It is, however, to be noted that the sinuses in the female specimens are not markedly smaller than in the males, averaging in the antero-posterior, transverse and vertical diameters 22 mm., 28 mm., 18 mm.; being, roughly, 1 mm. less in each diameter than the males.

Age.—Many of the ages given are estimated and may not be absolutely accurate. I do not find, however, any ground for the statement which has been made that the size of the cavity increases with age, this opinion is based on those cases in which the correct age was known. So far as my observations go, age gives no clue whatever to the size of the sinus; many old specimens presented large sinuses, while the reverse was often the case. The number of specimens used in taking the average age was 81; the average of this series is 47 years.

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

[1] Lancet, Lond., 1891, p. 1277.

Nationality.—As might be expected in a collection of this description, the nationality is in most cases unknown. Specimens 28 and 29, both from Indians, present large nasal fossæ and well marked sinuses. Specimens 76 to 84, which are from a collection kindly loaned me by Dr. J. F. Fairbairn, are all from the postmortem room in Vienna. They are rather under the average in size, and have been classified under the heading "Austrian."

Method of Making Observations.—In the majority of cases a sagittal section was made as nearly as possible in the median line, as this gives the best general view. I wish to draw attention to the fact, however, that inasmuch as a sagittal section is the one usually shown in text-books and illustrations, the idea is gained that the antero-posterior diameter of this cavity is much greater than the transverse. This is not correct, so far as my experience goes, as the transverse diameter is slightly greater than the antero-posterior. There is more room for lateral expansion of this sinus into the wings of the sphenoid bone than posteriorly, and when the expansion of the air chamber takes place in the anterior direction, it usually does so as enlarged posterior ethmoid cells.

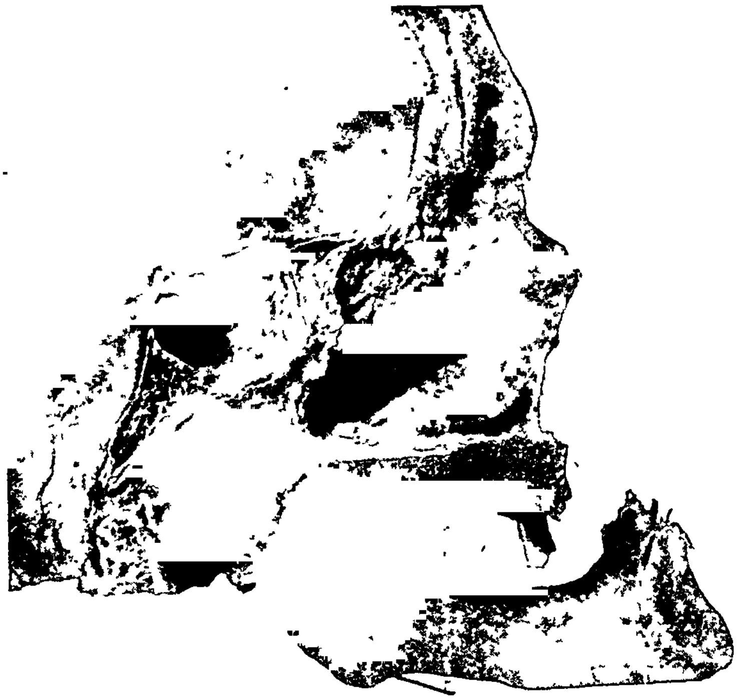

Fig. 1.—Typically placed large sphenoidal sinus. Note extremely thin posterior wall and small frontal sinus.

The coronal sections were cut about the middle of the pituitary fossa. A few horizontal and oblique sections were made, but they are not so satisfactory as the sagittal or coronal. The sectioning was done by means of an exceedingly fine hand-saw to minimize the injury to the delicate walls.

Situation of Sinus.—This is most frequently found in the anterior and upper part of the body of the sphenoid bone (Fig. 1). It is also found occupying the whole of the body in not a few instances (Figs. 2 and 5). It may be said, however, that the line of demarcation between the occipital and sphenoid bones is not well marked, and it is difficult to limit the body of the bone exactly. An analysis of the position shows the following:

Occupies whole body in 29 instances. about 30 per cent.; occupies the anterior and upper part in 51, about 60 per cent.; occupies the center of the body in 3 instances; extended into the basilar process in 2 instances; entirely absent in 1 instance; in 3 cases it was situated laterally in the body; in 1 case it was so far forward and so small as to make it doubtful whether it was the sinus or a posterior ethmoid cell. Some of the above are classified under two headings, e. g., as extending into the basilar process, and also occupying the entire body of the sphenoid.

Antero-posterior Diameter.—Utilizing 81 specimens presenting an obtainable antero-posterior diameter, the average was found to be 21 mm. (17/20 inch.) Excluding the Vienna series, in which the antero-posterior diameter was universally small, the distance was 23.25 mm. (24/25 inch).

Transverse Diameter.—Taken in a series of 70 specimens in which it was possible to take the complete diameter, not merely by doubling the half diameter, gave 29 mm. (1 3/16 inches).

Vertical Diameter.—Taken in a series of 75 specimens, gives an average of 18 mm. (¾ inch).

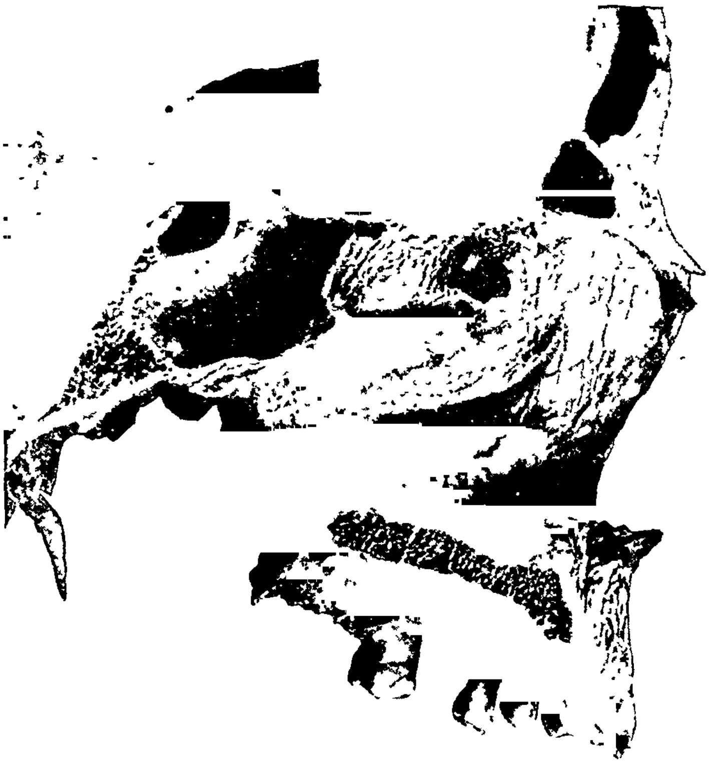

Fig 2.—Typical reniform sinus, large sphenoidal accompanying large frontal sinus.

Thickness of the Sinus Walls.—From the fact that in many of the specimens the walls had been injured somewhat, I have made no exact averages, but as would be expected, the anterior wall is much the thinnest, being largely made up of the delicate sphenoidal turbinate bones. From observations made on most of the specimens I would estimate the average thickness of the anterior wall to be, in the dry specimens, not more than from .25 to .50 mm. (1/100 to 1/50 inch). The roof of the sinus varies in thickness more than the anterior wall. It is sometimes as thin as .25 mm., but is oftener approximately 1 mm. in thickness, rarely is it over 2 mm. thick (1/12 inch). The floor is, as a rule, thicker than either of the other boundaries. The thickest portion of the floor is almost always found posteriorly (Fig. 1). due to the fact that the body of the sphenoid is buttressed on the basilar process of the occipital posteriorly and inferiorly. The thickness of the floor ranges from .25 mm. to 9 mm. (1/100 to almost ⅓ inch). Rarely is it as thin as the first mentioned figure, however. The thickness of both the floor, and more particularly of the posterior wall, depends, in large measure, on the position of the sinus in the body of the bone. As has been pointed out, in about 60 per cent. of cases the sinus is placed decidedly forward, which increases the thickness of both the posterior wall and the floor, but particularly the former.

The thickest part of the posterior wall of the sinus is always found on the same level as the floor. Thus, in operating in this cavity, the possible danger of penetrating the posterior wall is lessened by avoiding the upper part of the sinus wall posteriorly. The variation in the thickness of the posterior wall is from .25 mm. to 10 mm. (1/100 to 2/5 inch). The same sinus may present a great difference in thickness between the upper and lower parts of the wall.

Distance of the Anterior Wall of the Sinus in Front of Hamular Process.—This process appears in the form of a hook which is directed downward and outward from the lower extremity of the internal pterygoid plate. It forms the pulley-like arrangement about which the tendon of the tensor palati muscle winds. It can be felt directly behind the last upper molar tooth, and may give some information as to the situation of the sinus from below. I have found that the anterior wall of the sinus usually projects in front of a plane drawn vertically through these processes (Fig. 6); in no case did I find that it fell posterior to this plane. The average distance in front of this plane was 7 mm. (slightly over 1/4 inch). In 9 instances it corresponded with this plane. In 26 it was impossible to estimate it. These skulls were not sawed in a frame or from definite angles, so that at times, there was difficulty in striking a perpendicular plane from which to estimate this point.

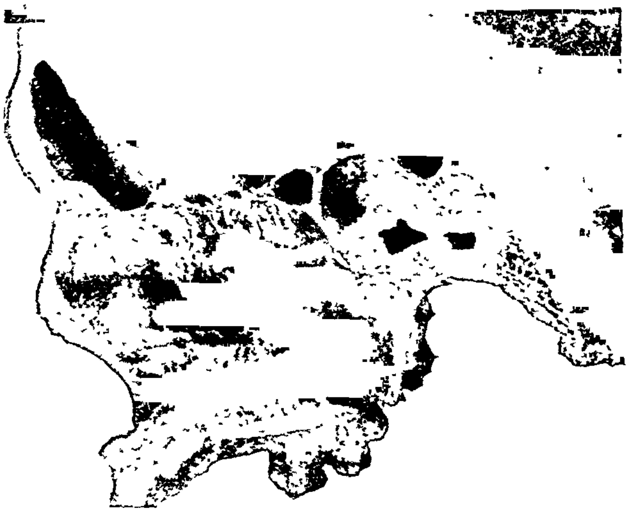

Fig 3.—Sinus with very thick bony lamina placed somewhat to one side, large frontal sinus

Thickness of Bone Between Optic Foramen and Cavity of Sinus.—The distance between the optic foramen and the sinus was taken in many instances. This was done with the view of drawing attention to the close proximity of important nerve and other structures which might possibly be affected by disease of the sinus. The bony wall at this point is very thin, varying from .25 mm. to 1 or 2 mm., and averaging not over .5 mm. (1/50 inch).

Distance Between the Anterior Wall of the Sinus and the Inferior Extremity of the Nasal Bone.—There are a number of circumstances which modify this distance, as well as the one which follows it. Some of these are, (1) the degree of prominence of the nasal bone; (2) the position of the sinus cavity in the sphenoid, the more anterior this is the less the distance; (3) the number and size of the ethmoid cells, the larger and greater the number, the farther back will the anterior wall of the sinus be, and, (4) the conformation of the skull in a general way, especially its antero-posterior diameter.

In estimating this distance, the lowest part of the nasal bone was taken, and the most anterior part of the anterior wall as nearly as possible equidistant between the inferior extremity of the nose and the anterior nasal process. The average obtained from measurements in 80 specimens was 57 mm. (2½ inches). The greatest distance was 64 mm.; the least distance was 40 mm.

Distance Between the Anterior Wall of the Sinus and the Anterior Nasal Spine.—The same series of 80 specimens was used and gave an average of 57 mm. (2½ inches). The greatest distance was 71 mm. (2¾ inches); the least was 45 mm. (1¾ inches.)

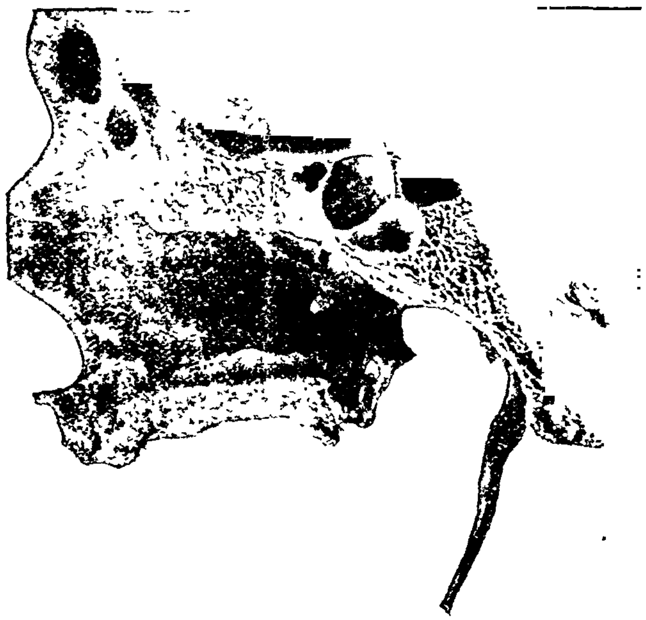

Fig 4.—Shows sinus placed anteriorly and superiorly inclining to the vertical type.

Size of the Posterior Nares.—Considering the relation borne by the posterior nares to the sphenoidal sinus, it had struck me that there might possibly be some relationship in size between them. Small posterior nares might occur because of a large sinus, and vice versa. There were utilized for this comparison 47 specimens, most of them dry, which would give a slightly greater measurement than the recent specimens. The average transverse measurement was 27.1 mm. (1 inch). The average vertical measurement was 25.59 mm. (about 49/50 inch).

It was observed that quite frequently there was considerable difference in the measurements made on the two sides of the posterior nares. This was more noticeable in the recent, but was also appreciable in the dry specimens.

As a result of this comparison, I may state that no relationship was observable. There were specimens presenting small nares with small sinuses; there were also large nares concomitant with large sinuses. This feature cannot be counted on to give any information as to the size of the sphenoidal sinus, the reason for this being that the sinus, when enlarged, extends laterally, forward or upward, and not downward.

General Shape of the Sphenoidal Sinus.—This depends very largely on the shape of the body of the sphenoid bone; in many instances the cavity is of an irregular form. On observation, after a sagittal section has been made, the most common form is somewhat reniform, with the concavity upward (Figs. 2 and 5). This occurs in the specimens in which the entire body of the bone is occupied by the sinus; the next most common type is a more or less vertical or upright one which occurs in those specimens in which the cavity is placed somewhat anteriorly (Fig. 6); this variety presents a thick posterior wall at the lower part. There seems to be a third type in which the cavity is located centrally in the body of the bone and which may be irregularly ovoid in shape. There are also a certain few sinuses which are extremely irregular in shape. The reniform type is rather apparent than real, for in many cases the transverse diameter exceeds the antero-posterior (Fig. 8). Specimens 6, 7, 76, show a marked transverse diameter, in one case involving the great wings of the sphenoid.

Laminæ.—Usually a vertical, more or less, median lamina is presented (Figs. 3 and 7). This, however, may be displaced either to the left or right and is frequently obliquely placed. This lamina divides the sinus into two parts, and so far as my observations extend, there has not been any communication between them. I have not found any undue preponderance in size of the right over the left portion, or the reverse. Many small subsidiary laminæ are seen springing from the walls of the sinus (Figs. 4 and 5), usually the posterior and external walls. These are directed forward and inward and vary much in appearance; they may be thick and strong, or thin and delicate. Sometimes they occupy a more or less horizontal plane. They serve to strengthen the bone, and also produce pockets or fossæ in the sinus. Some specimens are absolutely devoid of any suggestion of a lamina. Others present almost a reticulated appearance, due to the number and complexity of their laminæ. In one or two specimens the median vertical lamina was so thick and dense as to make it impossible to break it down by anything but a chisel (Fig. 3).

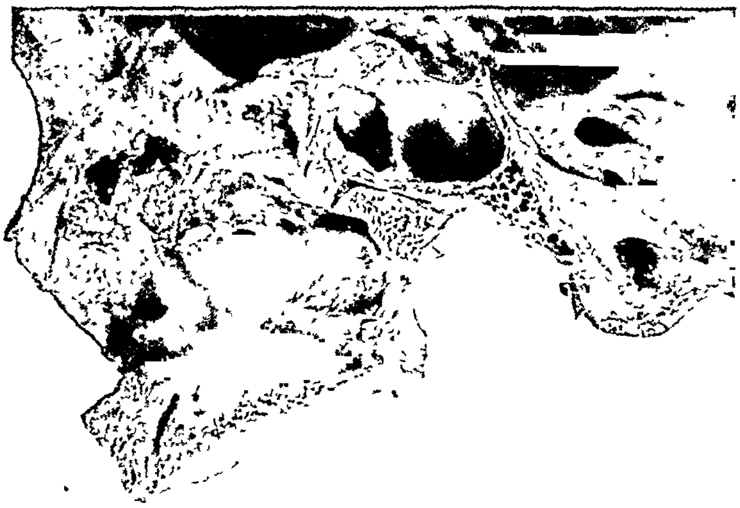

Fig. 5.—Shows diverticulum 25 mm. (1 inch) deep extending into pterygoid process and encroaching on sphenoidal fissure.

Diverticula were found in 55 of the 85 specimens and by far the most usual situation of these was in the pterygoid processes (Figs. 5 and 6); 25 specimens showed diverticula invading this process. In 26 cases, the right side of the sinus was marked by diverticula, and in 21 the left. The orbital cavity ranks next to the pterygoid process in the frequency with which it is approached or invaded, there being 15 cases in which it was involved. It is to be remembered in this connection that the orbital process of the palate bone very frequently contains a cell. This cell may communicate with the sphenoid sinus, and in these instances, is practically a diverticulum extending forward from the sinus into the orbital cavity to a greater or lesser degree dependent upon the size of the orbital cell; in fact, it is not unknown for the sphenoidal and maxillary sinuses to communicate with each other by means of this cell. The walls of the cell are exceedingly thin and, as a result of this arrangement, there is a very close relationship between the posterior part of the orbital cavity and the sphenoidal sinus.

The anterior clinoid process was invaded in 4 cases; the posterior clinoid process in 1 case; the ethmoid process in 1 case; the sphenoidal fissure in 1 case; the foramen rotundum in 1 case; the basilar process of the occipital bone in 3 cases. In 2 cases the diverticula approached very closely the cribriform plate of the ethmoid. The deepest diverticulum measured (Fig. 5) was 25 mm. (1 inch); there was also one measuring 14 mm. (11/20 of an inch). Diverticula in normal conditions would be a matter of little interest, but in disease, if pus were present, they would complicate the case and render drainage difficult. It is also a question whether a diseased sinus might not cause trouble in the orbit in those cases where they are closely approximated.

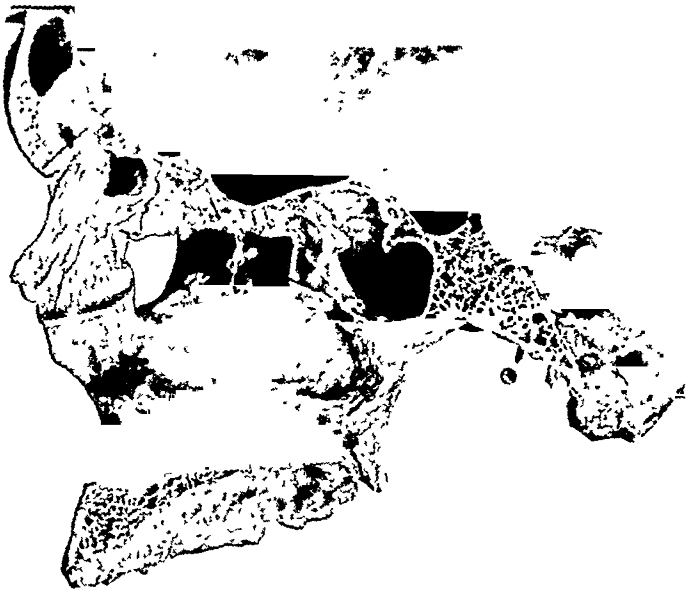

Fig 6.—Shows vertical type with diverticulum and concomitant large maxillary and frontal sinuses.

Communications.—The openings from the sphenoidal sinus, as a rule, lead into the upper and posterior part of the nasal fossæ. They are usually situated a little more than half way between the floor and the roof in the anterior wall of the sinus, being more frequently of an oval shape and set somewhat obliquely. In size they vary from 1.5 mm. by 1 mm. to 8 mm. by 5 mm. (extreme measurements in my series). The average was 4.6 mm. by 3.5 mm. Leaving out the extremes and based on a general observation, 6 mm. by 3 mm. (¼ by ⅛ inch) would seem to be the size of the opening most commonly met with. In many cases, however, the opening is circular in form. When oval the openings usually approach each other at their upper extremities. The openings sometimes communicate with the posterior ethmoid cells. This was thought to occur in one of my cases, but owing to injury to the specimen it was impossible to be sure of this fact.

A condition quite often is present in which the posterior cells are large and over-ride the sphenoidal sinus (Fig. 5). When this is so, the opening must almost of necessity take place into the ethmoid cells. In one specimen, No. 65, a very curious condition obtained. In this case there were two openings, oval in shape, 6 mm. by 4 mm. in size, leading through the floor of the sinus into the nasopharynx. These openings were of regular outline, placed symmetrically on either side of the vertical median lamina, and were additional to the two openings usually found communicating with the nose. Whether these openings were the result of disease or not I am unable to say. There is also present in this case a very large and irregular opening into the maxillary sinus which looks like the result of disease. The individual was a male of 36 years, who died of lateral sinus thrombosis.

Both openings into the nasal fossæ are not always on the same level. In specimen 69 there is an irregular opening on the left, and an oval opening at a somewhat higher level on the right side. The size of the opening in the dry specimen is no criterion of its size during life, for in very many cases the mucous membrane is found to overlap the bony opening and render it much smaller.

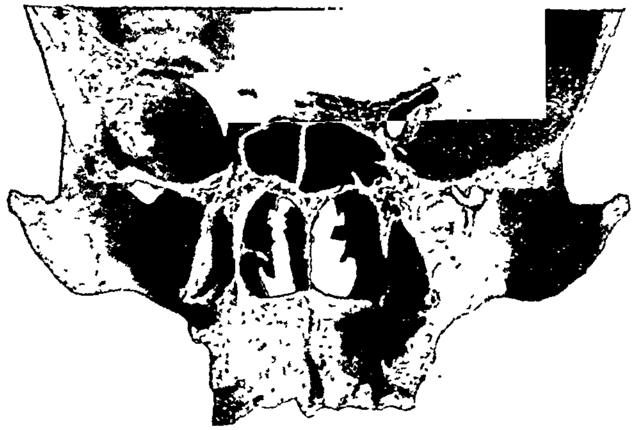

Fig. 7.—Coronal section through sinus, showing vertical median lamina and opening into posterior part of nasal cavity.

Interesting Features.—Under this heading, I will take up various points not included in the headings on the large outline. The first point is whether there is any definite relation in size between the bony sinuses of the skull; that is, given a small sphenoidal sinus. does it follow that there will be found a large maxillary or frontal sinus to compensate for the smallness of the sphenoidal? It is almost impossible accurately to compare the size of these sinuses; it would be a task of great difficulty to take their cubic contents, so that these findings are the result of ocular comparison only and not of systematic measurements.

I have found that quite frequently a large sphenoidal sinus is concomitant with large frontal and maxillary sinuses (specimens 5. 7, 12, 13, 14. 20. 30. 35 and 53). There are also a number which show sphenoidal and frontal sinuses occurring concomitantly (specimens 10, 21, 27, 32, 39, 55, and 67). Specimens are also found in which small sphenoidal sinuses and large frontal sinuses are associated in the same skull, and vice versa. I think, therefore, that it can not be said that any definite relationship in size obtains between the different bony sinuses of the skull. I believe that it would be impossible to forecast with any accuracy the probable size of the sphenoidal sinus if the size of the frontal and maxillary sinuses were known.

As to the question of the relationship between the size of the posterior nares and the sphenoid, my specimens do not show anything definitely characteristic. In specimens 2, 3, 7, 8, 14, 15 and 53, the size of the posterior nares is greater than the average, and yet there occurs also a large sphenoidal sinus. In specimens 10, 16, 19 and 28. the diameters of the posterior nares are below the average, and there is also a small sphenoidal sinus. This is to be accounted for by the fact as mentioned before, that the size of the sinus is increased more in the transverse and antero-posterior directions than in the vertical.

In specimen 4 there is seen an extremely thin plate of bone of not more than .25 mm. (1/100 inch) separating the sinus from the sphenoidal fissure; at the inner angle of the fissure there is situated the ophthalmic vein with the sixth, fifth, third and fourth nerves in the order given, from within outward.

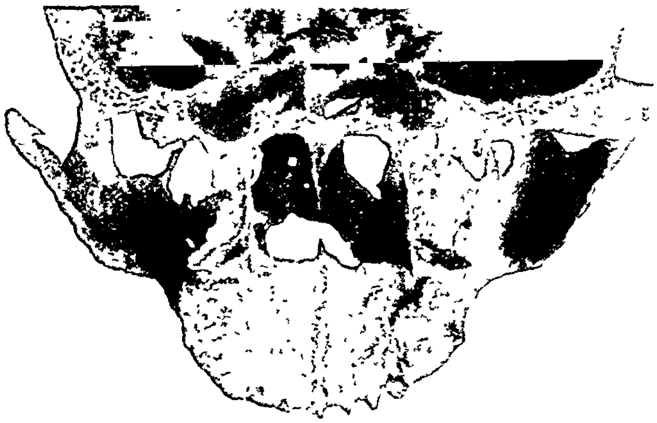

Fig 8—Coronal section through sinus of extreme width, showing involvement of lesser wings of the sphenoid bone.

In specimen 7 a sinus of extreme transverse diameter is seen invading the great wings of the sphenoid (Fig. 8).

In specimen 11 is a large diverticulum, 14 mm. wide at the base, invading the pterygoid process of the left side, and contrary to what might reasonably be expected. The left posterior nares is much larger than the right, and the width is greater than the average. This is important as showing how little one can be guided in one's estimation of the size of the sinus by the size of the posterior nares. An interesting fact is that any operation approaching the sinus by way of the post-nasal space and from below would be unsatisfactory in many cases from the fact that the floor is sometimes quite thick, and that the sinus is often situated far forward (Fig. 4). (Some examples of the difficulty of such an operation are specimens 17, 19, 20. 22. 24, 34. 40, 51 and 52.) I have tried to pass a probe from the anterior nares into the opening of the sphenoidal sinus in many of the specimens and find that in most instances it can not be done without the removal of some portion of the nasal turbinates. In some few cases, where the turbinates were very small, it could be done.

Any rule for the passage of a catheter into the sphenoidal sinus must necessarily be imperfect if for no other reason than that the nasal turbinates vary greatly. Added to this is the liability of variation of the sinus opening. Adding the minimum distance from the anterior superior nasal spine to the shortest antero-posterior sinus I get as a result 57 mm. (2⅛ inches). This will give the least distance from the anterior nasal spine to the posterior wall of the sinus, and furnish a conservative distance to which an instrument may be inserted without fear of entering the cranial cavity.

I would point out, in conclusion, that clinically this sinus is analogous to the tonsils in that it stands in such a position that it is prepared to receive and transmit infection primarily entering by way of the nose or nasopharynx.

I desire to express my thanks to Dr. A. T. Kerr, of Cornell University, Ithaca, for the loan of a series of nine specimens; also to Dr. J. F. Fairbairn, of Buffalo, for a similar loan of nine specimens, as well as to others who have loaned single specimens for use in this work.

170 Mariner Street.

THE PRESENT STATUS OF THE RADICAL OPERATION FOR EMPYEMA OF THE SPHENOID SINUS,

WITH DEMONSTRATION OF A NEW INSTRUMENT.*

ROSS HALL SKILLERN, M.D.
PHILADELPHIA.

Rhinologists concur in the opinion that when pus is being secreted by one or more of the accessory sinuses of the nose giving rise to symptoms, in spite of continued conservative treatment, a radical operation is imperative for a permanent cure. By the term radical I mean an operation which not only opens the sinus, establishing free communication with the nasal cavity, permitting thorough inspection and treatment, but which also prohibits, so far as we are able, a reinfection, or, in case a reinfection occurs, which allows the sinus to heal of its own accord with no discomfort to the patient other than the symptoms of an ordinary acute rhinitis.

The surgical relations of the sphenoid sinus from a rhinologic point of view embrace naturally those structures which are encountered during an operation in this region. We know if a straight line is drawn from the anterior inferior nasal process over the exact center of the middle turbinate it will strike the anterior wall of the sphenoid sinus (Zuckerkandl's line). While a number of German rhinologists[1] have taken exception to this line leading to the ostium of the sphenoid, nevertheless it will invariably strike either the anterior wall of the sphenoid, as Zukerkandl himself states, making no mention of the ostium, or the wall of a spheno-ethmoidal cell, which to all intents and purposes may be reckoned as a sphenoidal sinus divided by a horizontal partition.[2] The distance between these two points, according to Grünwald[3] and Hajek,[4] rarely exceeds 8 cm.; indeed, if one has passed a sound in this direction, 7.5 cm. in small heads or 8 cm. in large heads, measuring from the anterior inferior nasal process, the ostium and the sphenoid sinus are almost certain to have been penetrated.

The position of the ostium in the wall of the sphenoid sinus determines largely the possibility of sounding without more or less injury to the middle turbinate. The opening usually lies in the upper third of the anterior wall, the seat of predilection being deep in the spheno-ethmoidal fissure. The closer it lies in proximity to the septum (sphenoid rostrum) the more favorable the locality for sounding and the lower the ostium is situated in the anterior wall the deeper the sound will penetrate the sinus.

The position or condition of the middle turbinate also plays an important rôle in the procedure. Under normal circumstances the convexity of the posterior half hides the anterior wall of the sphenoid completely from view, and not until this has been removed and the pars nasalis of the anterior sphenoidal wall brought to view can an operative procedure be carried out in the neighborhood of the posterior olfactory fissure with any degree of safety. On the contrary, an atrophied middle turbinate or one which is strongly rolled inward certainly contributes to the difficulty of the operation. Deviated septums, septal spurs and ridges, polypi, etc., may add considerably to the difficulties previously mentioned. Suppose, then, under some favorable circumstance, we were able to see most of the anterior wall or pars nasalis by means of anterior rhinoscopy, the only remaining structure which might prevent the ostium from being visible would be the superior turbinate, and then only in the event of a deep spheno-ethmoidal recess, the ostium lying laterally and deep in the pars ethmoidalis. It is by no means necessary to have the ostium in view while endeavoring to pass the sound, but to my mind it is absolutely demanded when operative measures are about to be undertaken;[5] the anatomic relations of the superior wall to the optic nerve and pituitary body and the lateral walls to the sinus cavernosus and carotid artery, to say nothing of the brain itself, makes this region of operating one of extreme danger unless the operator has perfect vision of the entire field. Chiari[6] states that it rarely happens that one is required to open the sinus when the ostium is invisible. The various radical operations performed by operators at the present time have the same end in view, i. e., complete removal of the anterior wall of the sinus. This prevents any return of the disease, so far as retention symptoms are concerned, thus making the sinus practically continuous with the lateral wall of the nasal cavity. The ways and means employed, however, are many and varied. The operation is best performed under cocain, although some English writers[7] prefer choloroform. Operations may be divided into: 1. Extra-nasal, (a) frontal, (b) maxillary, (c) oral. 2. Endo-nasal, (a) indirect, (b) direct.

THE EXTRA-NASAL OPERATIONS.

Frontal.—Opening the sphenoid through the frontal sinus is not performed unless the frontal is diseased and is but a step in that operation.[8] Opening through the ethmoid from the internal angle of eye. This operation was first suggested by Grünwald,[3] later by Kuhnt,[9] and is only to be recommended in those rare cases of ethmo-sphenoid disease where there is present bulging of both lamina papyracea and nasal wall, with severe ocular symptoms, the endo-nasal operation having already been carried out with no relief to the patient.

Jansen's Method.—Jansen,[10] of Berlin, makes a large opening in the canine fossa through the mouth, resects the medial wall of the maxillary sinus, together with the middle and inferior turbinate. The ethmoid and finally the sphenoid sinuses are now opened. The sphenoid is curetted and the entire cavity tamponed from the maxillary sinus, the oral opening being closed after the second or third tamponade. Berens[11] uses Jansen's method when there is marked deflection of the septum toward the diseased side, especially at its posterior end, even when the antrum is not diseased. Furet's[12] method is the same as Jansen's, except that the ethmoid cells are not opened. The disadvantages of these operations are:

1. Needlessly opening a healthy sinus.
2. Danger of wounding structures situated in the fossa-pterygo-palatina and causing profuse hemorrhage and subsequent disturbance of the sensibility of the face.
3. Danger of injury to the optic nerve.

The objections to Beren's procedure are: 1. Owing to the great tendency of the sphenoidal sinus to contraction, it must be treated locally for at least six weeks after the operation. It is not a wise plan to keep the fascial wall of the maxillary sinus open for that length of time.

2. The deviation of the septum is so great as to require correction. The operation on the sphenoid could easily be carried out after the preliminary submucous resection was done.

Reichelt[13] reported a case in which he removed the anterior and inferior wall of the sphenoid sinus through the mouth. The objections to this operation are that the sinus is not always present, and the sinus often assumes sizes and shapes which make the method impracticable.

THE ENDO-NASAL OPERATIONS.

Indirect.—Killian's[14] method consists in resecting the anterior third of the middle turbinate; the bulla is then opened and the instrument pushed through the basal lamella of the middle turbinate and continued through whatever ethmoid cells are found in the way, finally reaching and opening the sphenoid sinus. This method can be carried out in those cases where the pars ethmoidalis of the anterior sphenoid wall is sufficiently broad, but the instrument must make a passage from the ethmoidal bulla to the posterior ethmoidal cells, as well as the superior nasal passage and the spheno-ethmoidal recess, before it can penetrate the sphenoidal sinus.

This procedure can easily miscarry when an unusually large posterior ethmoid cell is present, for, according to Onodi,[15] the sphenoid sinus is small in these cases and can easily be missed. The principal objection to this operation, to my mind, is the fact that one is always working in the dark, and on account of the many anomalies found in this region, no matter how proficient one may be in the regional anatomy of the part, the operation is dangerous.

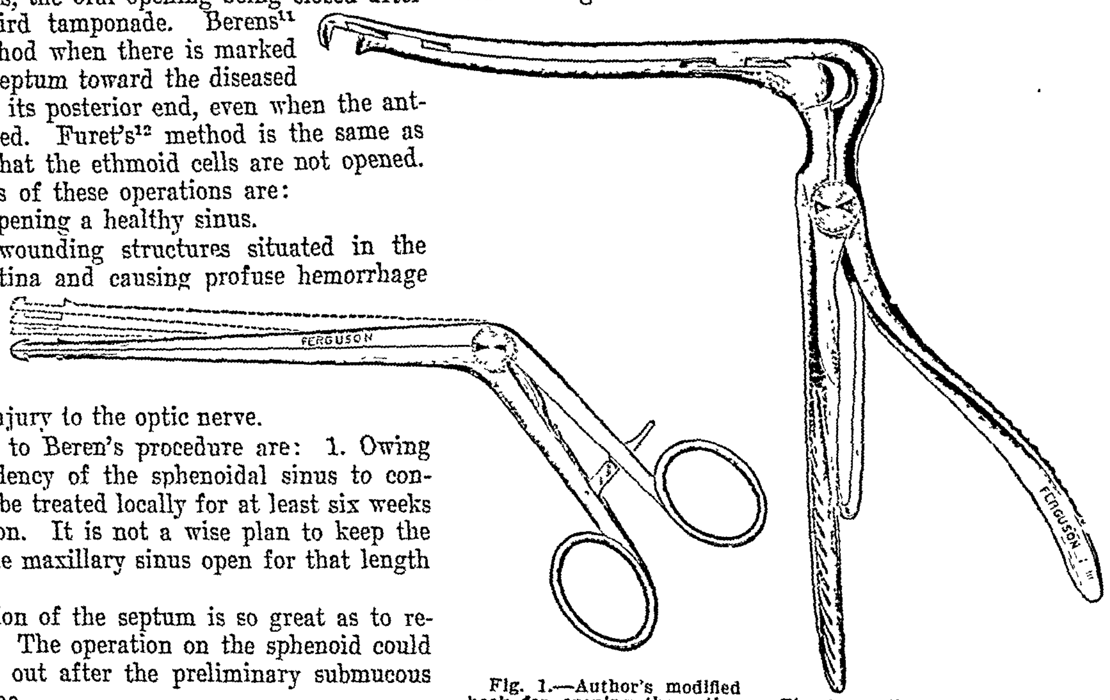

Fig. 1.—Author's modified hook for opening the ostium sphenoidale.

Fig. 2.—Author's modification of Hajek's bone forceps.

Shadle, of St. Paul, operated on the anterior wall of the sphenoid under control of a mirror held in the choanæ.

Direct.—This operation is preceded by a resection of the middle turbinate and often the posterior ethmoidal cells, the entire operative field being in plain view. Hinkel[16] breaks through the anterior wall with a sharp spoon, subsequently making the opening sufficiently large with a drill.

Schaffer[17] opens with an instrument similar to a sound and curette combined and apparently operates entirely by the sense of touch, for he says: "When one feels by raising and depressing the handle of the sound that the sphenoidal sinus lies fairly deep at its posterior end, after thorough cocainization, one introduces the spoon-shaped sound and presses the anterior wall of the floor until it breaks through, then removes the depressed splinters with bone forceps."

Ingals and Spiess[18] bore through the middle turbinate with a trephine. Douglass[19] says: "The best, safest and more rational method of opening the sphenoidal sinus is through the posterior ethmoidal cell. Stacke[20] uses an electric drill, a procedure which is simple and easily carried out, but requires a steady hand and an exact topographical knowledge; otherwise there is great danger of causing serious injury to the dura, optic nerve, internal carotid or sinus cavernosus. Zarniko[1] and Gmeinder[21] use a specially constructed chisel which is considered to be particularly adapted to those cases in which the posterior olfactory space is very narrow. Halle[22] uses a chisel and hammer to open the sinus, followed by an electric fraise to enlarge the opening. Stoeckel[23] also uses an electric fraise, but has had a special handle constructed similar to that of a pistol. He controls the current by means of the trigger and claims the operation can be performed easier than with Hajek's hook. The burs on the fraise are made with the cutting edges on the side.

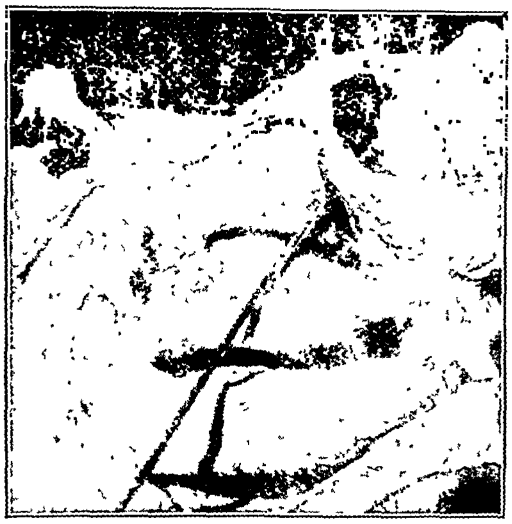

Fig. 3.—Probe passed into sphenoid sinus through natural ostium. Showing portion of middle turbinate to be removed.

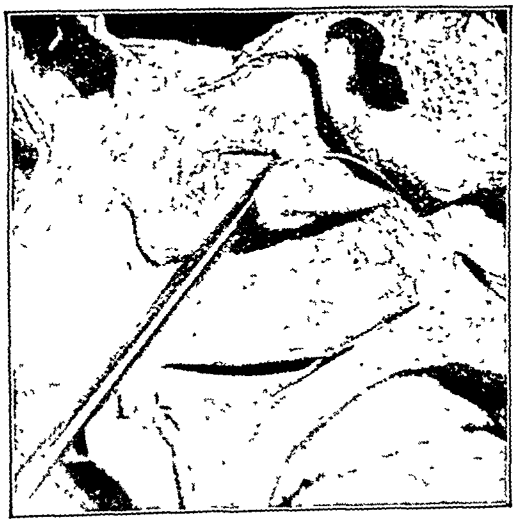

Fig. 4.—After the middle turbinate has been divided by the scissors, the snare is used to remove the posterior end.

Hajek's Method.[24]—Noting that the posterior ethmoidal labyrinth covered about two-thirds of the anterior wall of the sphenoid sinus (pars ethmoidalis) and that only one-third remained free (pars nasalis), Hajek conceived the idea to clear away first the posterior ethmoidal cells in conjunction with whatever part of the middle turbinate was necessary, which would leave the entire anterior wall in sight. He says:

> After complete anesthesia (local or general), I introduce my ethmoid hook into the posterior part of the rima olfactoria against the anterior wall of the sphenoid sinus as high as possible without using the slightest possible force. Since the point of the hook is always directed inferiorly in an injury to the lamina cribrosa is absolutely excluded. I then turn the hook so that the point penetrates the internal wall of the ethmoid labyrinth. When I now press the handle of the hook against the septum I am sure that the hook has penetrated deeply into the ethmoidal labyrinth. The internal (nasal) wall of the labyrinth with that portion of the middle turbinate which lies beneath is torn through by means of a strong pull on the hook. The pieces which remain hanging can easily be removed with a pair of good nasal forceps or the conchotomes of Grünwald or Hartmann. The advantage of the hook in this procedure is not to be underestimated. It is so slender that its point can be easily seen and followed during every phase of the operation, while the curette hinders the light and requires too much room. . . . The bleeding is usually trivial and is almost always controlled by wiping with sterile gauze. . . . I now proceed to resect the anterior wall of the sphenoid sinus.[25] To this end I use my bone forceps, but the ostium sphenoidale must have a definite width before we can introduce them into the sphenoid sinus. This I accomplish by means of my hook tearing the inferior edge of the ostium piece by piece until the opening is sufficiently large to permit the passage of the bone forceps.

This operation, with a few minor details, has always appealed to me on account of its practical soundness in keeping the operative field always before the eye. One phase of the operation I believe, however, susceptible to improvement, viz.: opening the ostium sphenoidale with a hook. As Zuckerkandl,[1] Onodi[26] and others have pointed out, the superior and lateral walls of the sphenoid sinus, so far as thickness and position are concerned, are in direct relation with vital structures and, indeed, it is not uncommon to find dehiscence of either of these walls where the cavity of the sinus is only separated from the cavernous sinus by a thin wall of mucous membrane. Holmes[27] and Onodi[28] report a number of sections where the optic nerve was contained within the sinus.

I noted, while experimenting on the cadaver, that in many instances it required considerable

pressure to force the hook through the ostium, especially where the opening was small and situated high in the posterior olfactory space. Often the hook would break through so suddenly that one had for the moment little control as far as its striking the superior or lateral wall was concerned. In these cases had a thin wall been present the overlying structures would only have escaped injury by the merest chance. With this thought in mind I had an instrument constructed (Fig. 1) which would obviate this difficulty. It consists of two long thin branches with a half knob on each end which when closed form a small ball. On pressing the two handles together these knobs open and lock at the desired width.

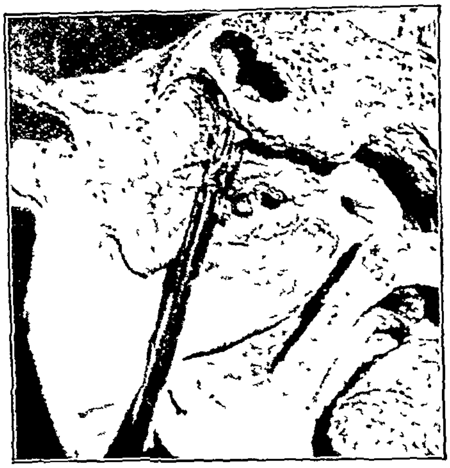

Fig. 6.—Removing the débris after the hook has been used.

This instrument, closed, is introduced into the ostium, being prevented from going through suddenly onto the superior or lateral wall[29] by a protector situated a few millimeters behind the knob, is opened by a slight pressure of the fingers and drawn out. The knobs are provided with a cutting surface behind which readily goes through the mucous membrane and thin bone. This procedure may be repeated until the ostium is considerably enlarged. When the bone is thick the operation can be finished by means of the excellent bone forceps of Hajek.[24] I have made a slight modification of this instrument (Fig. 2), having the nasal part bent to conform more with the position of the antero-inferior wall of the sinus.

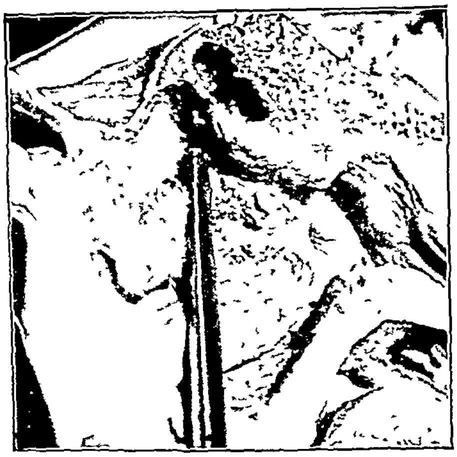

Fig. 7.—Introduction of the author's evulsor into the natural ostium of the sphenoid.

THE OPERATION.

The operation in detail which I find acceptable to all cases is the following: The lateral wall of the nose, including the septum, is thoroughly cocainized with a 20 per cent. solution, a few drops of adrenalin chlorid having been added. After anesthesia has reached the point beyond tactile sensibility the posterior half of the middle turbinate (Fig. 3) is removed by means of the scissors and cold snare (Fig. 4).

After bleeding is controlled by lightly wiping with gauze soaked in adrenalin chlorid, the superior nasal passage with the superior turbinate is exposed to view. Hajek's ethmoid hook (Fig. 5) is now employed after the method of the author,[4] and with two or three strong pulls the posterior ethmoid cells are broken through, the débris being removed with a Grünwald-Hartmann conchotome[30] or a similar instrument (Fig. 6). The sphenoidal sinus is now either exposed to view or opened completely up, depending on the anatomical construction of the part. Should there be present a spheno-ethmoidal recess, the ethmoidal portion of the sphenoid wall will remain intact; if, on the other hand, the superior turbinate forms most of the anterior sphenoidal wall, breaking it down will naturally expose the sinus. We will suppose, however, that, after removing the posterior ethmoidal cells, the anterior wall of the sphenoid has not been injured and we are able to see the ostium with pus oozing out. It is now an easy matter to introduce the evulsor[31] (Fig. 7), and with a few well-directed pulls to open the ostium 8 to 10 mm. in diameter (Fig. 8). The ostium is really never so small as it appears, because the mucous membrane, not only from the nasal side but from the interior of the sinus, joins to make more or less of a diaphragm. The bone at this point is paper thin, gradually becoming thicker toward the base and basilar process. The bent forceps of Hajek are now used (Fig. 9) and as much of the bone removed as is necessary to insure a permanent opening which, in my opinion, should reach as deep as the floor of the sinus (Fig. 10).

No structure of the nose shows greater tendency to granulate after operation than does this sinus and, after making a large opening, one would be surprised to find this opening, in the course of a few weeks, almost closed by these granulations[32]—not the sinus itself filled, but the ostium occluded. On

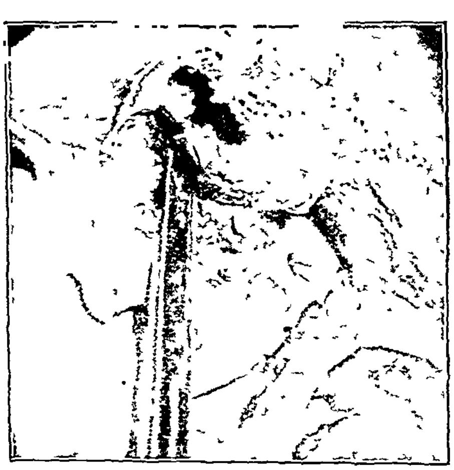

Fig. 8.—Drawing the evulsor out after opening it, thereby enlarging the opening in the anterior of the sinus.

---

[29] In those cases of "shut in" empyema, where the ostium is occluded, there usually is present pulsation of that thin membranous portion of the anterior wall previously occupied by the ostium. In any case the use of the sound will demonstrate the former position of the ostium.

this account the operations through the bulla, posterior cells and those making small openings are not to be recommended. The condition of the mucous membrane is frequently found to be swollen, velvety and nodulated. Under such circumstances it is better to wait two weeks and observe whether this inflammation will not subside of itself. If granulations remain at the end of this time, the floor of the sinus may be gently curetted after cocainization, but never the superior or lateral walls. Concerning the use of the curette in this sinus, authors are at variance. Hajek[4] and Onodi[15] condemn the practice, while Zarniko,[1] Schaffer,[17] Stacke,[20] Bresgen and others carry it out, but all agree that it is dangerous, particularly on the superior and lateral walls, and should be done with all gentleness and caution. I agree with Hajek, that it is, for the most part, superfluous and may be dispensed with, except in chronic cases where localized spots resist healing.[32] The bleeding which occurs is minimum and can easily be controlled.[24] Four cases have been reported in which postoperative bleeding from the anterior wall occurred.[16, 24, 33, 34] This was controlled by tamponade in all except that of Myles. His, however, required ligation of the external carotid

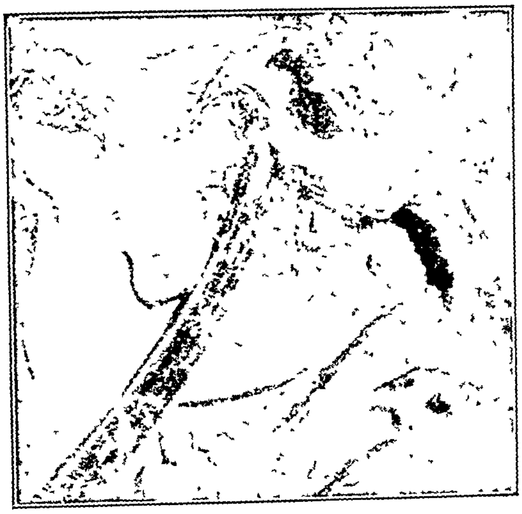

Fig. 9.—Hajek's modified forceps biting away the anterior wall piecemeal; last stage of the operation.

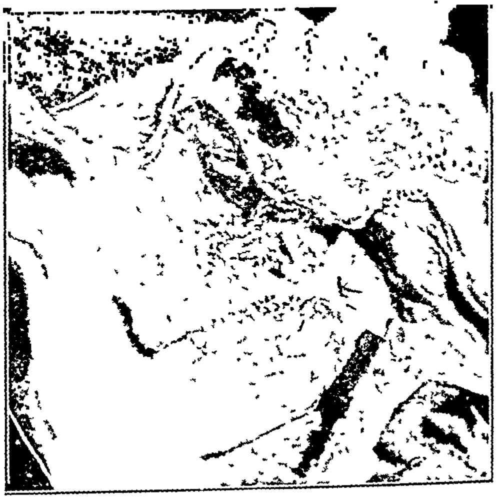

Fig 10.—Result of complete resection of the anterior sphenoidal wall, after the operation.

If, on the other hand, the resulting hemorrhage becomes copious, syringing with a 1 to 100 solution of citric acid or pressing a cotton tampon soaked with adrenalin in the sinus will control the bleeding. The disadvantage of the latter procedure is the tendency to secondary hemorrhage. As a precautionary measure in these cases a tampon of iodoform gauze prevents reactionary hemorrhage. The tampon is removed after 48 hours. This danger is, nevertheless, slight when one considers that the only artery standing in the way of being injured is the nasopalatine, running over the floor of the body of the sphenoid. Zuckerkandl states that this is the smallest branch of all the turbinal arteries.

The sinus cavity is now swabbed out with a gauze tampon soaked in hydrogen peroxid, a little thymol iodid (aristol) insufflated and a piece of cotton laid in the anterior nares.[35] Tamponing of the cavity is a personal equation with the operator. Hajek[24] rarely uses one, Schaffer[17] and others invariably follow this line of treatment; in any case only loosely packed iodoform gauze is used. The subsequent treatment[36] consists in washing out the sinus with a warm boric acid solution.[37] observing that the mucous membrane returns to normal and, above all, to prevent granulation tissue forming on the edges of the wound,[38] the object being to keep the opening permanent, thus to permit free drainage of secretion which may subsequently form.[39] To this end after ten days the edges should be lightly cauterized with chromic or trichloracetic acid, continuing every week until they are fully scarred over, which usually requires about six weeks. Edematous swelling of the mucous membrane may occur after application of the acid, but they are quite evanescent and vanish without special treatment. Complete healing usually takes place in from three to eight weeks, depending on the degree of inflammation and extent of operative interference.[40]

The advantages of this operation are:

1. The field of operation is always in sight.
2. The preliminary opening of sphenoid from within outward thereby incurs no danger to structures behind.
3. There is a permanent opening which lessens the danger of recurrence.

ABSTRACT OF DISCUSSION.

ON PAPERS OF DRS. GIBSON AND SKILLERN.

Dr. Albert H. Andrews, Chicago: I was interested in the measurements and averages given by Dr. Gibson, but as I listened I imagined a patient sitting before me with pus trickling down his posterior pharyngeal wall and perhaps some

H.: Who reports a case in a girl of 18, who, after a simple syringing out of this sinus, was confined to her bed for two days with most violent pain and vomiting and all the symptoms of meningitis, with the exception of the temperature, Laryngoscope, 1904, 866. Undoubtedly dehiscence of the superior wall existed in this case.

[38] After the operation the edges of the removed portion of the sinus wall are naturally bare and must become entirely covered with fibrous tissue before the secretion ceases This new scar tissue will consist of two layers, a ground layer of fibrous tissue and a superficial layer of epithelium. The fibrous layer is formed from the granulations which spring out of the bone, while the epithelial layer grows from the neighboring mucous membrane over the fibrous or granulating layer. A normal healing can only occur when these layers grow in harmony. Should the epithelial tissue grow slowly, the granulations from the bone will become too strong to be covered and coalesce, thus again closing in the sinus. As a gauze packing in the cavity stimulates these granulations, it should be dispensed with in the after-treatment.

lesion of the eye, and I wondered how much good those averages would do me when I came to consider his case. Averages are all right from the anatomic standpoint, but from the clinical standpoint—when one works with the brain immediately above, and dangerous blood vessels immediately at the side, and nerves which one must let alone in close contact with the cavity—averages are of no value. It is the individual case which is to be considered. In doing some cadaver work it occurred to me that the posterior pharyngeal wall and the back wall of the sphenoid cavity form the arc of a circle, of which the anterior nasal spine forms the center. In making measurements it was observed that the distance from the nasal spine to the posterior pharyngeal wall was practically the same as to the posterior wall of the sphenoid cavity. If one can pass a probe in the direction of the sphenoid sinus as far as he can pass it directly backward, he must of necessity be in the sphenoid cavity and no place else. It seems to me this is a better rule than any other measurements can be.

While the curved forceps shown by Dr. Skillern has the advantage of allowing one to cut downward a little more, it interferes with the turning of the forceps to one side, as one must do to enlarge the opening laterally, as one can not well turn a curved forceps sidewise in the nose. An anatomic arrangement which must be borne in mind in cutting away the anterior wall is this: The anterior wall close to the septum is very thick and strong, while on one side a little out, one-third or one-fourth of an inch, it becomes very thin, as suggested, sometimes only membranous. These cavities should be explored very much more frequently than they are. By using a probe with a bend it can be done in the majority of cases without the necessity of removing the middle turbinate or resorting to any other surgical procedure, and it has happened to some of us to find a great many more cases of sphenoid disease since we have made the exploration of the sphenoid a part of our routine examination.

Dr. Ross H. Skillern, Philadelphia: In answer to Dr. Andrews, the forceps can easily be turned when in position, and I think can be entirely rotated while in the nose. One is thus enabled to bite in any direction. The curve is not sufficient to interfere in any way with mobility.

ALVEOLITIS OR SOME PATHOLOGIC CONDITIONS ARISING FROM INEFFICIENT CARE OF THE MOUTH.*

M. H. FLETCHER, D.D.S., M.D., M.S.
CINCINNATI.

Civilization brings with it the necessity of conscious intelligent care of the body, in order that good health may be enjoyed for the allotted three score years and ten. This is particularly true in case of the teeth.

I believe it possible, by the proper selection of prepared foods, to live a moderately healthy life without teeth, yet to live under such conditions could hardly be called enjoying good health. To have good teeth and healthy gums is one of the first requisites of perfect health. The belief that everybody can secure this condition, even by proper care, may be utopian, but this ideal can be nearly attained by most persons. Not only this, but a large percentage of diseased teeth and gums can be restored to comfort and usefulness by proper treatment and continual cleanliness. If every surface of every tooth could be kept perfectly clean one would have neither decayed teeth nor diseased gums. It is rare to see a mouth as clean as it is practicable for one to be kept, yet much time, money and energy are spent for luxuries and fads, and much is also paid to doctors and dentists for the repair of ills that could be prevented by conscious, intelligent care.

To take no care of the teeth, or inefficient care, seems to be almost a universal habit. One patient put it very nicely when she said: "I find I have been cleaning my conscience all these years instead of my teeth."

Among the most prevalent diseases, as well as the most surely preventable, is that which attacks the alveolar process, resulting in its necrosis and the loss of the teeth. This disease is known by several names, but commonly by that of pyorrhea alveolaris. In my opinion it is almost wholly brought about by calcareous deposits which can be kept off by the patient.

NOMENCLATURE.

The names by which the disease is and has been known are serving their purpose, but for simplicity and clearness the usage in other branches of surgery and medicine will be adopted. That is, the name of the organ or part involved will form the foundation or generic name, the nature of the disease being indicated by a suffix, and the stage or condition by a descriptive adjective. Under the name "gingivitis," inflammation of the gums follows the same rule.

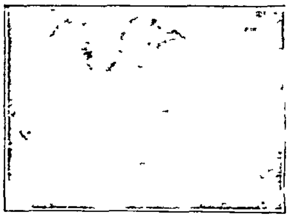

Fig. 2.—First lower molar lost from alveolitis. Second is beyond recovery. Third has recovered.

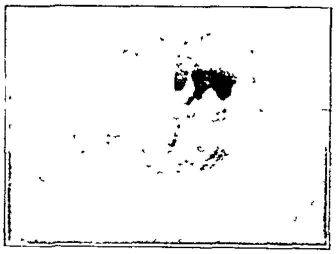

Fig. 4.—Lower first and second molars. The first molar and bicuspid have been curretted, the second molar has not. Picture taken three months after treatment. Typical of many cases.

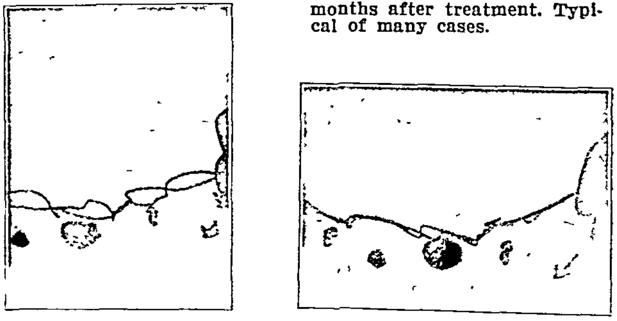

Fig. 3—Superior incisors and canine after curetting. With wire splints to sustain them until recovery.

The alveolar process being the part primarily involved in the disease under special discussion, the term "alveolitis" will be used in this paper in the sense above indicated, and the different stages of the disease distinguished as acute, chronic, suppurative and necrotic alveolitis. The adjectives "tuberculous," "syphilitic," "pyemic," etc., are also usable under this plan, and each ascribes a definite pathologic characteristic to the disease whose name it modifies.

Riggs' disease is a better term than pyorrhea alveolaris, since the latter name describes only the suppurative stage, and does not permit of use to describe other stages without producing a paradox or a contradiction. Such terms as "Bright's disease" and "Graves' disease" are, however, being eliminated from general medicine, and purely descriptive terms, formed on the principles indicated above, are being substituted.

---

* Read in the Section on Stomatology of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

* Owing to lack of space, the article is here abbreviated by the omission of parts of text and illustrations. The complete article appears in the author's reprints.

The term "interstitial gingivitis" is subject to the criticism that it implies that the soft tissues are the ones primarily involved by the inflammation, whereas in this disease the bone seems to control the health or disease of the soft tissues overlying it. Subsequent to the initial lesion in alveolitis, the gums seem to have little more to do with the disease than the skin does in cases of underlying bone disease.

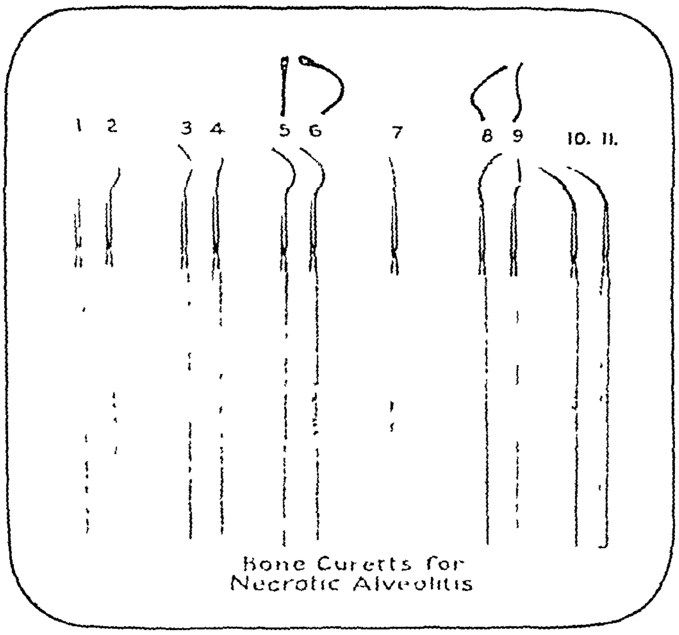

Fig. 6.—Bone curettes for removing dead and diseased tissue about the teeth and in deep pockets. The longest ones will reach beyond the apices of the roots.

PATHOLOGY.

Alveolitis in its progress includes all the processes known to other surgical diseases of bone, viz., acute, chronic, suppurative and necrotic stages. In my opinion, the initial, exciting cause, in at least nine-tenths of the cases, is the formation of calcareous deposits about the necks of the teeth. The tartar being adherent, Nature can not remove it, and the inflammation becomes more extended and violent, resulting in raw tissue and open blood vessels at the point of contact with the tartar: this naturally results in the formation of pus, in small quantities at first. The surrounding of a foreign body by pus or the floating of a foreign body in pus until the surface is reached and an opening made for its discharge, is a familiar process in the case of a thorn or splinter in the flesh.

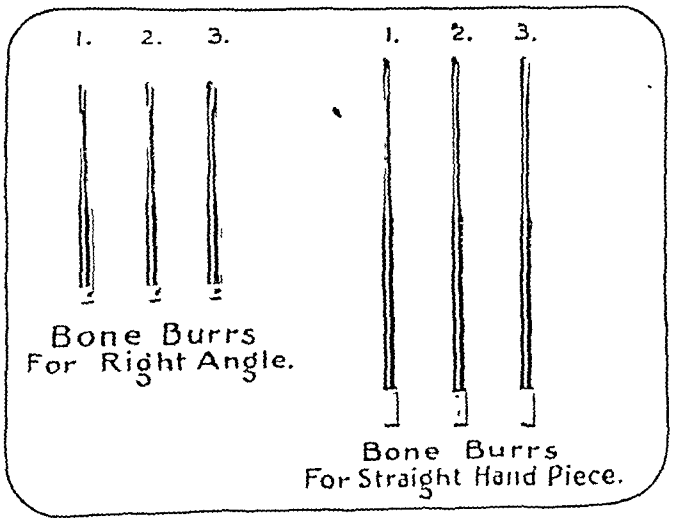

Fig. 7.—Alveolitis burs for both straight and right-angle hand pieces, for the same purpose as the curettes. The burs work more rapidly and thoroughly and are usable in a majority of cases.

Tartar against the gum margin is a foreign body, and Nature endeavors to dispose of it just as she would the splinter. The tartar, being fixed, only continues the irritation, with pus as a continual result. The thin edges of the alveolar process, being continually attacked by pus or osteoclasts, soon begin to melt away, and the membranes covering the bone and roots of the teeth disappear with it. So long as the irritation remains, this process continues, its rapidity varying with environment and individual. Thus it is seen that Nature in this particular malady, if unassisted, in her attack on her enemy, the calcareous deposits, destroys the tissue about teeth until the tooth with its attached tartar is extruded, thus finally accomplishing what she started to do (Fig. 3).

The acute or incipient stage of alveolitis may continue for a lifetime, with no appreciable inconvenience or pain to the patient, the progress often being so slow that there is nothing to reveal the presence of the disease aside from the receding of the tissue about the necks and roots of the teeth. But infection may take place about one or more teeth at any time, producing periostitis, either inside or outside of the socket, proceeding from one stage to another, ending in necrosis either of limited or extended degree.

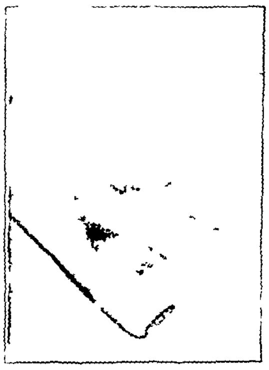

Fig. 5.—Superior molars and bicuspids when antrum is involved. The wire passes through the opening into antrum.

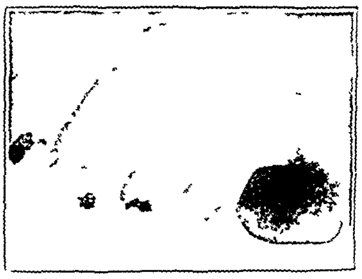

Fig. 8.—The case reported in which disease from superior lateral had perforated to floor of the nose.

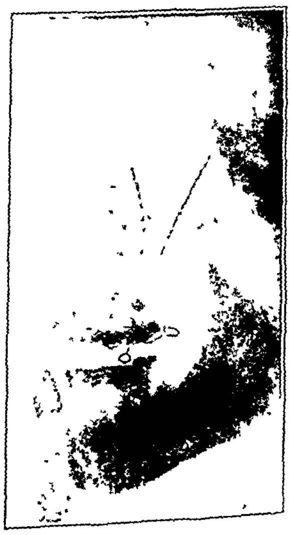

Fig. 9.—Showing a typical case in which necrotic alveolitis has perforated the antrum above first molar. The wires show the opening into the antrum to be about the diameter of the crown of the tooth. Typical of thirteen cases.

ETIOLOGY.

Abundant evidence can be presented to maintain the position that, without local irritation, destructive diseases of the soft and hard tissues about the teeth and alveolar process would be confined to those due to traumatisms, thrombosis, nutritional changes and bacterial stomatitis, with now and then an infection from the circulation, as in other tissues; but these affections would then be attributed to their special causes and treated accordingly.

The most frequent point of attack for alveolitis is in the septums between the teeth, where tartar is not disturbed by lips, tongue, food or brush; but any place about the necks of the teeth, where tartar is undisturbed, is apt to be the point of attack (Fig. 3).

The opportunity for the entrance of infection to the alveolar process is almost unlimited, for calcareous deposits about the necks of the teeth are found in every adult human mouth and in the mouths of most children.

The quantity of tartar and the irritability of the soft tissues in its presence varies in different individuals, and with each individual according to his power at different times to resist disease after its onset.

Autointoxication or lack of resisting power, however caused, makes one more susceptible to other diseases as well as to this; but a low state of health could hardly be the sole cause of an infectious disease. The microbes of infection are ever present in great abundance, Miller having isolated more than one hundred different kinds of bacteria from the juices and deposits in the mouth. So, when the gums and periosteal membrane are sore and bleeding from the impingement of tartar, bands, the wedging of food, or any other irritant, infection may readily start and the disease follow. Lesions of the gums about the teeth are so universal that the wonder is, not that there are so many diseased mouths, but that there are not more.

A lesion of the gums, because of immediate proximity to the bone, seems pre-eminently a suitable place for the beginning of any of the surgical infections of bone. The infections to be considered in alveolitis are those that produce osteomyelitis, caries or tuberculosis of bone, gummata or syphilitic lesions, and actinomycosis. The ultimate result in each one of these infections is dead bone.

Necrosis from lead, mercury, phosphorus and all other chemical causes, are not to be considered here, since their etiology is apparent.

The diagnosis, then, in any single case, lies between an infection by pus-producing germs, such as accompany osteomyelitis; tuberculous germs, which produce caries; syphilitic germs, which produce gummata; and actinomycosis. The last named produces "lumpy jaw" in cattle, and is not frequent in man, especially in this country. It is not uncommon, however, in countries where camels are used as domestic animals, and is confined largely to these countries. It is sometimes seen in cattle in the United States, and now and then in man in cattle districts; but in this paper it hardly need be considered in the light of a factor in alveolitis.

Then, in consideration of the above, we have three kinds of bacteria to consider as the most probable sources of infection, namely, pyogenic, tuberculous and syphilitic.

SYPHILIS.

The consensus of opinion seems to be that syphilitic infections are far less numerous than either pyogenic or tubercular infections. In my opinion this is especially true in regard to the alveolar process, although the mouth seems particularly favorable to other lesions of syphilis. In patients who seem to be syphilitic, recovery is much slower, the infected tissue being more sensitive, and persisting in showing inflammation long after other patients with other infections have recovered. The characteristic thickening of the periosteum in the gummata of syphilis can be felt over the diseased bone in the neighborhood of the apices of the teeth, either on the buccal surface or inner surface, or both. Gummata in the periosteum must be distinguished from hardened lumps at the apex of dead teeth or exostosis of bone. Gummata usually appear, however, on the septum of bone between the roots rather than over them. This is because syphilitic bone is more apt to be in the cancellous portion of the body or between the roots. These conditions are rare, however, in comparison with pyogenic and tuberculous infection. Local treatment is practically the same in all infections, excepting that it must be continued longer in syphilis. Syphilitic infection may be either congenital or acquired. The congenital form appears more frequently in the bones of children, and particularly in the long bones, but the acquired form frequently shows in the bones of the head and face, the alveolar process and maxillæ being no exception. With our present incomplete knowledge, however, syphilitic alveolitis is not easy to distinguish from tuberculous alveolitis.

OSTEOMYELITIS.

In considering osteomyelitis, which is pyogenic, it is to be remembered that in a typical case the seat of trouble is in the marrow of one of the long bones, oftenest the thigh bone of a child or youth, although it may occur in the periosteum, in the form of a felon, for instance. It is considered that the infection comes from the blood and oftenest finds a lesion or point of least resistance in the marrow of some bone and begins its work there. The bony walls being unyielding, the patient's suffering is intense, and the spread of the infection to the surrounding marrow and bone is rapid. The destruction and pain continue to increase as long as there is no exit for the pus and other products of inflammation. Early interference by the surgeon is demanded here, for if time must elapse for the pus to burrow its way to the surface through bone and flesh, many days at least, and probably many weeks must pass, during which time much tissue is destroyed and untold suffering endured.

The above description, if somewhat modified, applies to an abscess at the apex of some dead tooth, or an infection under the gum tissues, either from the blood or by infection from a lesion at the alveolar border. Very acute and painful infections about the alveolar process imply that the pus is confined at some depth below the margin of the gums. If the infection were nearer the gum margin, either in the socket or on the alveolar process, the discharge would either not be confined or would make its exit at an early stage of the disease, giving comparatively little pain in either case. The infection remaining, however, continues its destructive work, and a chronic stage of suppurative alveolitis or true pyorrhea alveolaris is the result.

If not interfered with, this condition may continue indefinitely, now and then assuming an acute stage when new foci become infected, quieting down again when the sinus is opened to the surface. But each time this occurs there is loss of more bone in the alveolar process or in the deeper cancellous portion, often extending into the body of the jaw, and many times into the antrum. This destruction continues slowly or rapidly, according to the acuteness or chronic activity of the disease, until the tooth or teeth are lost. When the tooth is out, if the infection is not mixed with other germs, such as tuberculous or syphilitic, healing becomes prompt and complete in the normal time for the building of bone structure, that is, in two or three months. Under proper surgical treatment, however, healing can be made just as prompt and complete, and the teeth retained and made useful, provided the dead and infected bone be removed before the foundations of the tooth are too greatly destroyed (Fig. 4).

TUBERCULOSIS.

In considering tuberculous infection as a cause, my experience makes me believe that alveolitis in all its stages, after its initial lesion, is more largely due to this infection than to any other.

Descriptions, by two of our best authors and surgeons, of this disease in other bones than the alveolar process, will better serve than my own, as a description of tuberculous alveolitis and its ravages. The action of tubercle bacilli on bone, as here described, is particularly applicable to carious alveolitis.

Park[1] goes into minutiæ in regard to the "infectious granuloma" of Virchow, which plays so large a part in the slow destructive process in caries of bone. This granulation tissue is the effort on the part of Nature to repair the damage done by tuberculous or other infection, but the granules also become the seat of infection and serve as a further means of increasing the progress of the disease, especially that of tuberculous type. Carious necrosis into the alveolar process and jaw bones seems exactly the same in character and extent as this infection in other bones, and in my hands has yielded to the same character of treatment that has proved successful on other bones (Fig. 4).

Although many microscropic tests have been made. no satisfactory results have been obtained. Probably none can be obtained until the work is taken up under proper laboratory environment for both culture and microscopic tests; and even then the work might be uncertain, as Miller has shown[2] in his endeavors to find a special bacterium of this disease. He sums up his work as follows:

> From these experiments, we might conclude that, if there is a specific bacterium of pyorrhea alveolaris, it does not readily grow on gelatin, a result which is of value in so far as it indicates that in further experiments on this subject, media should be employed which admit of being kept at the temperature of the mouth. *At the same time the thought suggests itself that possibly the bacterium of pyorrhea alveolaris, like so many mouth bacteria, is cultivable on none of the artificial nutrient media, which would of course render all experimenting useless.*

TREATMENT.

In the first place, in extensive cases, the tissues will need to be cocainized, a 5 to 10 per cent. solution being injected into the pockets. If the tissues are very sensitive, a weaker solution can be injected into the gums, the same as when teeth are extracted. The periosteum is very sensitive, but bone is not so, and dead bone not at all so. The use of cocain must be determined by the conditions. I use it as sparingly as possible, for the reason that if enough is used to produce anesthesia it usually produces a sleepless, disagreeable effect, if it does not prostrate the patient for a day or two. Usually the cocain can be postponed until the point of curetting and burring is reached.

Next, all calcareous deposits must be removed. There are hundreds of instruments made for this purpose, each operator having his own preference in instruments and his own methods of use. But the deposits must be most thoroughly removed and the teeth and roots polished with an orange stick and pumice, floss, discs or brush, or whatever the operator can best use to restore the teeth to a smoothness equal to that they originally had.

Experience shows that scratches and grooves on the roots from instruments are nearly always present. although they should not be. These scratches, when under the margin of the gums, do not cause the roots to decay nor prevent the tissues from becoming healthy; but calcareous deposits remaining, however slight in amount, will continue to irritate and increase, resulting in a repetition of the various stages of the disease, namely, initial lesion, increased inflammation, infection and destruction of bone. One of the most important parts of the treatment consists in teaching the patient how to keep the teeth free from calcareous deposits. If tartar is not allowed to form about the gum, it will not form below, and the disease is prevented; otherwise it is likely to return (Fig. 1).

After removal of deposits comes the removal of necrosed bone. No repair is ever complete unless this is done. It is oftenest done, however, by Nature herself *without intentional aid from the doctor.*

Now. it would seem the rational thing for the physician to seek out the points of attack, and by conscious effort to assist Nature by tearing down and removing her enemy's citadel, the infected and dead bone, be it ever so small an amount, thereby reducing the enemy's forces and stimulating Nature to a renewed and stronger effort, and thus not only shortening the time of repair, but making it more sure. In this way recovery can be induced in many cases which would otherwise end unfavorably. The progress of tuberculous infection in bone is so slow that many patients, even if not entirely cured, may be much relieved, in that the disease becomes quiescent, and the affected teeth, which otherwise would be lost, remain useful for years.

The conscious effort referred to consists in the use of delicate bone curettes and suitably shaped burs for removing dead bone from about the necks and roots of affected teeth. Examination should first be made about the neck of every tooth with a delicate probe; one of the bone curettes is usually good for this purpose, but a more delicate instrument, like a smooth broach, is often necessary. The sense of touch readily reveals the presence of bone not covered by soft tissue. When such is present there is very little if any sensitiveness, whereas if gums or periosteum still cover the bone, the patient quickly responds to the pain and the touch reveals the difference between live and dead bone. No matter what one may believe as to the causes of the disease, the fact remains that, in the mildest cases of alveolitis in its second or chronic stage, there is always more or less death of the bone about the teeth, and the dead and diseased tissue should be removed in order to give Nature the most assistance.

The third or necrotic stage is that in which the alveolar process is more deeply involved, the necrosis usually progressing along the root in one tract, until near the apex, then gradually encircling the root, also continuing its ravages into the maxilla. In the upper jaw the infection often goes into the antrum, now and then into the floor of the nose. and many times destroys large sections of the cancellous portion of the superior *maxilla* (Figs. 5 and 9).

In the treatment of these cases, packing is not called for except in instances of extensive removal of tissue, such as curetting the antrum or the removal of considerable portions of the body of the bone.

If systemic treatment is demanded it should be directed toward the restoration of normal health by such means as the elimination from the diet of foods which do not become wholly digested and assimilated. and the copious drinking of pure water. If the local trouble is complicated with other diseases of moment, the general practitioner or specialist should take charge of these.

TIC DOULOUREUX.

Besides these deep-seated extensive cases, there is another class which calls for knowledge of local pathology and great keenness of diagnosis. They are nonsuppurative and attended by more or less neuralgic pain, sometimes a matter of small discomfort, again reaching the magnitude of tic douloureux. They usually occur about a perfectly good tooth, and there is no evidence of inflammation, either on inspection or on percussion. The one symptom which calls attention to them is entirely subjective; that is, the patient complains of discomfort or pain in the neighborhood. The tooth affected is usually next to one more deeply affected or next to the space where one has been lost. With a smooth broachlike probe inserted close to the tooth some place will be found which is not sensitive, usually approximating the space where the adjoining tooth was, or the tooth more deeply affected with the disease. The bone is found nude of periosteum and eburnated, that is, abnormally hard. This hardened condition is easily detected by the touch; the bone is very hard to cut even with a bur, and is not sensitive. The treatment consists in the removal of the eburnated bone with a curette or bur; the bur is the better.

Disease of the periosteum, wherever found, is usually accompanied by neuralgic pains. In view of this fact, I have been led to believe[3] that tic douloureux might be due to a disease of the periosteum, starting as above described, and continuing even after all the teeth have been lost.

Subsequent experience has very much strengthened my belief in this theory, and I believe it lies with the stomatologist to work out this hypothesis and find the proper treatment for this most distressing malady. At the present time I would call this variety periosteal alveolitis from tubercular infection, or periosteal caries.

DIAGNOSIS.

The diagnosis of chronic cases of alveolitis needs suitable instruments, sensitive touch and great care; and the treatment, in addition to this, requires a perfect knowledge of the anatomy of the structures and their pathology.

To operate in any of these cases is surgery and not dentistry, so that the stomatologist also needs to be skilled in operative surgery to a degree which gives him suitable knowledge and confidence in himself to handle a patient undergoing the removal of part of the alveolar process either above or below. He must also be capable of opening and properly treating the antrum of Highmore, and of knowing if this cavity is diseased beyond its connection with the teeth, or whether it is diseased at all or not, and of handling a patient under collapse, either from shock or local anesthetic. Further, the operator should be so in touch with his patient and the extent of the operation as to know whether the operation should be performed under local or general anesthesia, and whether it should all be done at once or at intervals of a few days or weeks; for general and systemic complications from secondary and acute infection may occur at any time.

These features will present themselves more strongly when a history of some of the cases is given and the radiographs are shown.

INSTRUMENTS.

Under the impetus, first, of an effort to be thorough, then of surprise at the prevalent ravages of the disease, then of a desire to learn its full extent and how to treat it, I found myself bewildered at times. Consequently, I began to invent instruments which would reach the extended tracts of necrosis. These instruments are here presented for criticism (Figs. 6 and 7).

The curettes, or hand instruments (Fig. 6), are all of the hoe and hatchet type, varying only in size of blade and length and shape of shank. The attempt is made by these variations to reach any extended tract of necrosis. The necrosed portions are usually friable—that is, in the state of osteoporosis—and can easily be cut away with the curettes; but certain phases of the disease and certain kinds of infection often result in osteosclerosis; that is, hardened or eburnated bone, on which the curettes make little headway. For cutting these hardened bones I have made some extra long bone-cutting burs (Fig. 7), both for the straight and right-angle hand-pieces. The contra-angle seems to be more suited to the work, however, than the right angle. The burs for the contra-angle will reach all cases in the lower jaw and most of the upper, but a bur two and one-half to three inches long—that is, one long enough to reach to and into the antrum—is often necessary for the upper jaw.

Experience has taught me that the burs must be of the fissure-bur type, with rounded ends, and small enough to cut away the septums of bone without injury to the roots. Often this can not be done with any bur, since it would necessarily be so delicate that it would break very easily, an accident which occurs quite frequently. The same thing also occurs with the curettes. The alveolitis burs are made without the usual shoulder near the head in order to prevent them from breaking so easily. In many instances the roots of teeth are so close to those adjoining that no instrument sufficiently strong can be inserted into the space.

OPERATIONS.

On account of proximity to the floor of the nose, the antrum and the roof of the mouth, necrotic and suppurative alveolitis may be more serious in the upper than in the lower jaw, since all these cavities may be involved singly or at once. It has fallen to my lot to be obliged to remove much of the alveolar process and to excavate more or less extensively into the cancellous bone of the superior maxillary.

My records show that in the past twenty-two months I have treated 112 patients with necrotic and suppurative alveolitis. This does not include patients in whom moderate amounts of tartar have been removed and the teeth polished. Out of these 112 patients, in 13 the antrum was perforated; 17 had acute osteomyelitis; 8 a considerable portion of the alveolus and bone from the maxilla was removed; 5 had symptoms approaching tic douloureux; and all required more or less curetting of the alveolar process and maxilla. Twenty-four had one or more teeth that could not be saved. In one of the antrum cases the disease was caused by intranasal disorder and has been troublesome for five years. Two patients went to a nose specialist, and I do not know their later condition. In the other ten the conditions have been cleared up, as shown by transillumination, and the patients have been discharged, so far as antrum trouble is concerned.

---

[3] Fletcher, M. H.: Periosteal Caries, THE JOURNAL A. M. A., Sept. 2, 1899, xxxiii, 555.

Affections of the antrum caused by the teeth are much more amenable to treatment than when the disease is from intranasal disorder.

In one instance, in the lower jaw, it was necessary to remove all the teeth and alveolar process, back of the canine on one side, curetting extensively into the body of the bone. In another the patient was operated on by a general surgeon and much of the body of the lower jaw removed on one side, in addition to all the alveolar process from the canine back. The patient was afterward sent to me to have the upper teeth and jaw treated. I found extensive necrosis running back into the cancellous bone from above the superior lateral and central. The harder plates of bone under the floor of the nose and the antrum had not been perforated, but their shapes could easily be felt with the instrument. This patient has been under treatment for six months and is nearly well.

By proper handling, these patients can be conservatively treated and the structures often induced to heal without the radical operation of extended removal of maxillary substance, as is now so frequently done in the hands of the general surgeon.

The laws of regeneration do not permit of complete healing of bone tissue inside of several weeks at the shortest, and often require several months, so that patience and careful watching are necessary on the part of both patient and doctor. One patient now on my list for nearly a year, who would not submit to a radical removal of the cancellous bone in the superior maxillary, has submitted to a small amount of removal from time to time and is gradually recovering under two dressing treatments a week. This case, however, was the result of a dental abscess arising at the apex of the superior lateral which had discharged into the floor of the nose (Fig. 8).

The extensive ravages of alveolitis must be seen to be fully understood, and it is my desire that stomatologists may take up this task and unitedly work out the complete history of the disease, together with the most approved methods and instruments for its successful treatment.

REGENERATION.

At the present time, the greatest uncertainty about alveolitis is in regard to the origin of the cause or the kinds of infection producing it. The symptoms are nearly the same in all instances, and the treatment is practically the same in all cases, namely, the removal of deposits and of any necrosed or dying tissue, which constitute the hindrances in Nature's path to recovery.

After curetting and burring have been done, the cavities should be washed out with a warm antiseptic solution to remove the cuttings. The blood should be allowed to clot in the cavity. My plan is to be careful not to disturb the blood clot so long as it remains aseptic. If there is a tendency for pus to form, the wound should be washed out every one, two or three days, according to conditions, and, if pus continues after ten days, a second, third or even more attempts must be made to remove the offending material.

Aseptic blood clot is Nature's "false work" or scaffolding on and into which she builds all new tissues, no matter of what kind. The less the healthy clot is disturbed, the more prompt is the repair. In the blood clot is formed the granulation tissue of repair, which is the second stage of the building of new tissues. Any disturbance to these granules is also a hindrance to repair; hence packing is seldom called for.

Following the formation of granulation tissue is its gradual change into tissue of the kind from which the granules sprang. This process continues until the wound is healed. The hindrances to this normal process are foreign bodies, dead or dying tissue, and the presence and increase of bacteria. Nevertheless there is a continuous and never-ceasing effort to extrude or to tear down and carry away any foreign body.

This new or granular tissue thus endeavoring to envelop the diseased or dead tissue is called the involucrum. Dead tissue thus completely involved is attacked from every point, and often an enemy thus attacked can be destroyed, whereas, if only partly surrounded, it would hold its ground.

This process is one of the most common things to be seen in the human mouth, especially in patients who have been or are being treated for alveolitis. When the crown of a tooth has disappeared, the involucrum begins to grow over the edges of the root, and at times a portion of the root may be completely enveloped and finally become absorbed. Inflamed gums, from irritation of tartar or other causes, constitute an attempt to involve and destroy the enemy and replace lost tissue.

And now to the point of the above explanation. What really happens in a large number of cases treated for suppurating or necrotic alveolitis is that an effort is made by the doctor to remove the deposits. Some doctors may try to remove dead bone. In any event, the tissues are wounded in the effort, and all or most of the deposits and dead bone removed and the limiting zone or membrane at least partly broken up. Thus Nature is stimulated to a new and vigorous effort to repair the damage done. The involucrum grows up and around the root, enclosing more securely any deposit that may have been left. Of as much importance, however, is any necrosed or infected bone which the involucrum may enclose, for it is likely to increase in extent and, as stated, many times involves the deeper portions of the maxilla, often reaching the antrum (Fig. 9).

If I have suggested anything new or valuable, I believe it is the necessity of either curetting or burring about all teeth where the disease is found, and of more thorough removal, if the disease is deep seated—that is, of consciously assisting Nature to do what she is always trying to do. These deeper-seated sequestra, however, do not always prevent the involucrum from closing tightly about the neck and roots of the teeth, especially if the involucrum is composed of bone tissue. In such a case, at some point about the tooth, dead bone may be found or a place which can be penetrated to dead bone or to a cavity above. This, however, can be done only with a delicate but sufficiently stiff probe such as I will show. A small portion of necrosed bone may be absorbed and complete regeneration finally take place after Nature has been stimulated to a new effort, but the approved surgical treatment is to remove all dead or dying bone if it be practicable.

It must be borne in mind that the process of regeneration of bone in these cases is accompanied by acute inflammation of the surrounding tissue. The new-forming bone is soft and yielding; the callus does not show much tendency to harden for three or four weeks, and does not become ossified for six or more weeks. Often, therefore, after the removal of bone about the roots, the teeth are looser than ever, and at times need splinting with wires to other and firmer teeth, the splint remaining until ossification is completed, when the teeth will become firm and useful, provided there remained in the beginning enough live bone, periosteum, and endosteum for the purposes of regeneration.

CONCLUSION.

In conclusion, I apologize for the length of this paper. To me, however, every portion of the subject is fraught with so much interest and clinical experience that it has been difficult to select that which seemed most necessary in presenting the subject.

The radiographs will somewhat support my practical experience, but only your own experience, past and future, can reveal to you the great prevalence and ravages of this disease.

11 East Seventh Street.

ABSTRACT OF DISCUSSION.

DR. EUGENE S. TALBOT, Chicago: Dr. Fletcher says that a large percentage of diseases of the alveolar process are of local origin. Here I disagree with him. He says, however, that "to have good teeth and healthy gums is one of the first requisites of perfect health." No one will dispute this statement. Perfect health, however, means health of the body, generally, as well as the mouth. Dr. Fletcher says that "the term interstitial gingivitis is subject to criticism since it implies inflammation of the soft tissues as being the primary tissues involved." The constitutional changes which cause this disease nearly always take place in the arteries, as demonstrated in my work on "Interstitial Gingivitis or So-called Pyorrhea Alveolaris," and, therefore, the bone is liable to be the first involved. The term "interstitial gingivitis" was given for the very reason that the disease was deep-seated; the word "interstitial" means between tissues including both hard and soft. From Dr. Fletcher's reasoning the word "alveolitis" is objectionable since it does not refer to the gums and soft parts which are always first involved when the disease is of local origin, as he asserts it is, in a large percentage of cases. The term "pyorrhea alveolaris" should be used only when pus is present. Dr. Fletcher ignores the autointoxications of pregnancy and those caused by drugs and diseases. Certainly arteriosclerosis and endarteritis obliterans, which are present in almost every case, are not local irritations. He says that a low state of health could hardly be the cause of an infectious disease. Researches have shown that the only infection which takes place in this disease is pus infection. The inflammatory process precedes this stage. Dr. Fletcher describes the effects of syphilis, tuberculosis and actinomycosis as infections and classes all pathologic processes as infection. These diseases may or may not cause infection of and destruction of bone, etc. Very few patients come to me for treatment suffering from these infections. Dr. Fletcher speaks about necrosis and necrotic tissue; asserts that tartar is the great cause; that "infection of the alveolar process is almost unlimited;" that "calcareous deposit is found in the mouth of every adult human and of most children." If it be due to tartar, how is the disease accounted for in animals which do not have tartar but which do have deposits, the result of the disease? My studies on animals and human beings have demonstrated that this disease (in the constitutional and large majority of cases) is the result of irritation in the blood, which sets up absorption of bone (not pathologic in the sense of necrotic), but precisely such absorption as results in the alveolar process when a tooth is extracted or in tooth movement. Dr. Fletcher forgets that the alveolar process is wholly unlike any other in the body, being a doubly transitory structure. Its end is annihilation. It is natural for this bone to be absorbed: not so with other bones. The alveolar process is only waiting for some slight irritation (not sufficiently active to cause necrosis) to set up absorption. This irritation is caused by changes in the blood stream (autointoxication and acidosis). Syphilis, tuberculosis, actinomycosis and all diseases will cause such changes in the blood, and always act on the alveolar process. Dr. Fletcher brings forth no researches in proof of the correctness of his premises. I still believe that there are local causes, but a large proportion are constitutional. It is my experience that regeneration of the alveolar process, if it does take place, is a process similar to that of bone absorption. If acute inflammation sets in the formation of osteoclasts and osteoblasts, halisteresis, and Volkmann's perforating canal absorption can not take place.

DR. G. V. I. BROWN, Milwaukee: When Dr. Fletcher uses the termination "itis," without modification, then he lays himself open to the necessity of accepting the well-known etiologic factors that come into play with reference to all inflammations. He would lead us to infer that he believes the questions of constitutional characters are very slight; but again he tells us that he does consider them important when he says that the cause is entirely local. His paper speaks of "autointoxication, or greater susceptibility to disease." The latter is not autointoxication, but may be a result of it. Do you believe for a moment that by any kind of scraping you could prevent the dark line appearing at the gingival border, or the effect on the structures of excessive mercury administration? Would scurvy do the same thing? I have shown several times a series of slides of an individual who had what under Dr. Fletcher's term would be alveolitis; of course he had alveolitis, but every organ in the man's body—heart, kidneys, liver, spleen—showed the same round-celled infiltration, the same destructive process going on as in the alveolar process, but worse in the alveolar process than elsewhere, because he had alveolitis the result of leukemia, which is a constitutional disease. I thought that everybody was willing to admit that where inflammation, especially of such a character as this exists, there are both predisposing and exciting etiologic factors. Dr. Fletcher gets good results from his treatment, and I am perfectly willing to accept his surgical principles and methods of treatment, because I know he knows what he is talking about. There is no difference between us except in the matter of trying to make it appear that this one factor, calcic deposits, so greatly overshadows the constitutional and all other generally recognized factors.

DR. STEWART L. MCCURDY, Pittsburg: The terms "caries" and "necrosis" denote incidents in the history of disease, and not diseases themselves, if we take into consideration the etiologic factors that produce disease. Caries of any tissue, hard or soft, is the result of some local or constitutional disease. Necrosis, likewise, implies a history of constitutional disease. We must go back to the etiologic factors that produce the disease rather than consider these as distinct diseases. From Keen's new work on surgery I find that primarily considered tuberculosis of the alveolar process is rather rare compared to syphilis and other diseases of this structure. I would like to apply the word "hereditary" rather than "congenital" to these diseases. Syphilis is rarely congenital. The syphilitic condition exists at the time of birth, but not the disease itself. "Congenital" means existing at birth, and "hereditary" means that the disease develops at any time in after-life, but that it was latent at the time of birth. The majority of these conditions develop later. I made the estimate in 1897 that 50 per cent. of all bone and joint diseases of children had syphilitic ancestry and this view was so radical at that time that the paper was not published; yet since that time many more radical papers than mine have been published. Most practitioners of medicine and surgery had not seen as many of those general syphilitic diseases as those of us who practice among railroaders, mill-workers and the laboring classes. Men who are in sky-scrapers do not see the cases that men see who are treating this class of cases.

DR. VIDA A. LATHAM, Chicago: The whole of this discussion goes back to the first principles. What is pyorrhea alveolaris, Riggs' disease, or interstitial gingivitis? Let us have a pathologic classification: in the lack of it lies our trouble! Dr. Fletcher is misunderstood by some people, Dr. Talbot by others, and I think that Riggs himself was misconstrued. The condition termed alveolitis exists as a later period. The disease starts with a gingivitis, and I believe that Dr. Fletcher's statement is true that thrombosis plays a part; that it is a primary factor: in other words, the vasomotor system losing control and being soon affected by thrombosis and the degeneration of the nerve fibers of the gingivæ, prevents contraction in some cases and gives advanced retraction in others, and thence result two forms of pyorrhea, if I may use that term: 1. the acute, with the spongy gum, bleeding, pus formation, with chronic suppurative alveolitis as the termination or sequela; 2, the chronic, in which there is typical fibrosis, recessional gum, with that peculiar black stain running around the teeth—few know what it is—which produces a mechanical abrasion that gradually causes the tooth structure to become less and less and the alveolar process may be denuded of the periosteum, and on top of that we get recession of the gum which finally exposes the cementum of the tooth. This form of gingivitis is seldom or never mentioned as a pyorrheal condition. I believe it is pyorrheal myself. Another reason why I think that this classification is going to be borne out is this: In both cases, whether of the pus-forming type or the fibrosis variety, there is eversion of the teeth. In some cases of fibrosis the teeth are turned right out, so that they have to be extracted instead of being replaced. I think that the fibrous form of alveolitis goes more particularly with Dr. Talbot's theory; when there is faulty elimination or metabolism accompanied by liver disease, very often cholangitis is present, and anemic areas in the stomach, and the pancreas is at fault. In these cases there is a change in the tooth structure showing that there is arteriosclerosis behind it.

Dr. Daniel Hopkinson, Milwaukee: I have frequently tried to isolate some organism as an etiologic factor in this condition, but have met with negative results. But I think that possibly another way of isolating organisms, as the tubercle bacilli, is by the inoculation of the guinea-pig. If we question whether a certain lesion is tuberculous or not, by inoculating a guinea-pig, say in the groin, we can positively state whether the tubercle bacilli are present; even if in few numbers they will positively develop in the guinea-pig. So far as the histologic changes in tuberculosis or syphilis of these structures are concerned, they are frequently identical. If, however, the *Spirochæta pallida* be found, and we are positive that it is the pallida and not any other spirochete, then we can state positively that we are dealing with a syphilitic lesion. But unless an individual has frequently found these *Spirochætæ pallidæ* and has been able to differentiate them from the other spirochetes present, such a diagnosis would not be reliable. Pus-producing organisms might possibly be isolated by another inoculation.

I think that the tubercle bacilli are very rarely, if ever, obtained in sputum in a pure type. Especially in the mouth we find almost every form of suppurative organism; therefore, if we are dealing with a tuberculous lesion, there is undoubtedly present a secondary infection with pus-producing organisms.

Dr. M. L. Rhein, New York: I believe that the apparent variance of opinions on this subject is due entirely to the fact that we have never had a proper classification or nomenclature of pathogenic conditions involving what may be termed the peridental aspects. The exciting cause ought to be recognized in the nomenclature and associated with it the predisposing cause. A good example for such a nomenclature is that adopted by the dermatologists. We have been discussing here a large variety of diseases and attempting to include them under one particular head. I thoroughly believe that a large number of diseases can be properly termed "alveolitis," with an adjective expressing the predisposing cause, just as well as I am assured that a large number could be as appropriately termed "gingivitis," with its proper predisposing cause expressed by an adjective. I am sure that the class of cases in which faulty metabolism is a predisposing cause is an entirely different class. Those are the cases in which the tooth has a tendency to become everted or protrude. The result of my investigations on that particular type of disease is that it is due to the abnormal condition of the blood which is circulating in the pulp of the tooth and acting as an exciting cause. Faulty metabolism of some kind produces an irritation that makes itself felt in the end circulation that we have in the pulp of the tooth. I have given considerable attention to the microscopic examination of pulps of this nature, and I have found in such cases the most remarkable pathologic conditions in the pulps of teeth that have never even been abraded on their exterior surfaces. The removal of such pulps has been sufficient to produce a cure of such conditions. Dr. Fletcher and Dr. Talbot are discussing different diseases. Nothing can better demonstrate the absolute necessity for this Section to produce a proper classification of the different diseases of the alveolar or, what may be a better term, peridental, regions of the mouth.

Dr. Edward C. Briggs, Boston: That interstitial gingivitis is an entirely separate thing from infectious alveolitis seems to me perfectly clear. There is no question that infection often supervenes in interstitial gingivitis and brings about the true infectious alveolitis which Dr. Fletcher describes. But that it exists as a first condition in all cases I could not concede. Interstitial gingivitis, as I understand it, exists where there are no deposits, and that is one thing that is often overlooked in the treatment—that many cases of true interstitial gingivitis show very little evidence either in the way of pus or of deposits. These cases of infection we see and may confuse them at first with cases of interstitial gingivitis. I have seen two cases of actinomycosis which at first I thought were severe cases of interstitial gingivitis. I proved them to be cases of actinomycosis, and subsequent surgical treatment cured the condition.

Destruction of the alveolar process is not necessarily always caused by inflammation, but is the physiologic condition due to any irritation that is set up about the alveolar process, as after extraction. So we get it in the irritation that comes in gingivitis. The first treatment of these cases of interstitial gingivitis is the removal of the pulp, which is the beginning of the treatment in a great many cases, to offset the pathologic changes.

Dr. M. H. Fletcher, Cincinnati: I agree with Dr. Rhein that the nomenclature is still unsatisfactory. I have plainly stated in the paper that the soft tissues are first involved and that the bone becomes involved subsequently. The word "gingivitis" indicates the earlier stages of the disease, in which the part would recover with the simplest treatment did not the bone become the foundation or primary factor in the chronic stages. At the present I believe that the use of "alveolitis" as a generic term allows of the best description of the diseases of the soft tissues by the use of qualifying terms, as described in the paper. The name, however, is insignificant compared with the pathology and etiology. Both Drs. Talbot and Brown ignore this and other parts of the paper in their discussion. Arteriosclerosis is given great prominence in Dr. Talbot's book as well as in his discussion. The terms "arteriosclerosis" and "endarteritis obliterans" are practically synonymous, the latter term being a description of the closure of the arteries in arteriosclerosis. This disease of the arteries and the high pressure that accompanies constitute practically a disease of the large vessels, not usually found in the capillaries, and yet the capillaries, smaller arterioles, and Haversian canals are the only blood vessels found in the tissues about the teeth. Faulty metabolism, from any cause, fosters and augments any existing weakness or lesion, and this was set forth in Dr. Briggs' paper as in my own. Dr. Talbot says that I "ignore the autointoxications of pregnancy, drugs and disease" as a special cause of the disease. I do not believe, as he does, that this is a special factor here any more than it would be in any portion of the body where a point of least resistance is found. If Dr. Talbot will read the paper more carefully he could hardly make the remark that I class "all pathologic processes as infection," and I refer him and Dr. Brown to the paper itself for answers to most of their objections and to a more full discussion found in reprints of the paper and discussion. Dr. Talbot further says: "Dr. Fletcher forgets that here is a condition wholly unlike any other part of the body, the alveolar process being a doubly transitory structure. Its end is annihilation. It is natural for this bone to be absorbed; not so with other bones." I can not see any foundation for this statement. If by "doubly transitory structure" he means that the alveolar process is gradually becoming obsolescent and thereby is deficient in quality of structure or lacking in resisting power. I differ with him most emphatically. According to the laws of evolution, if an organ is becoming obsolescent from disuse it gradually grows smaller, and may grow weaker as far as muscles are concerned, but it always receives the requisite amount of blood and is perfectly nourished, but each generation finds it smaller. Under natural selection many hundreds of generations are required to make an appreciable change in a genus or a species. I believe that the written history of man is not long enough to make evident much change in him. According to the laws of evolution the teeth would disappear before the alveolar process. The teeth stimulate its growth; when they are extracted the process disappears. If, however, new teeth were present in the jaw and were to erupt, the alveolar process would be rebuilt as in the second or third dentitions. In rodents, elephants and all animals that have teeth of continuous growth, the alveolar process is also continuously renewed, showing that in vertebrate types the alveolar process is anything but a weak or transitory structure. The tail of the tadpole might be called transitory, but up to the time when it begins to disappear it is well supplied with circulation and nourishment and is perfectly strong for its function.

[Limitations of space in THE JOURNAL necessitate abbreviation of the discussion here, but copies of the paper and full discussion can be obtained by sending to Dr. Fletcher.]

CIRCULATORY DISTURBANCES IN DIPHTHERIA.*

JOHN HOWLAND, M.D.

NEW YORK.

Matthew Arnold, in his "Essays on Criticism," says: "It is true that all time given to writing critiques on the works of others would be much better employed if it were given to original composition."

From the truth of this statement we must occasionally except the subject of medicine, for it is not the work of one man that is analyzed, but the opinions and hypotheses of many. These often give us information of great value in regard to matters which are insusceptible of direct experimental investigation, and from such an analysis we may often see the gaps in our knowledge that require to be filled.

It is not possible within reasonable limits to give a systematic discussion of the whole subject of the circulatory disturbances in diphtheria, but I wish rather to consider the underlying causes of these disturbances, some aspects of the symptoms, and the rational therapy indicated to oppose or counteract these underlying causes.

A thorough knowledge of the cardiac lesions which result from diphtheria is requisite for a consideration of the production of symptoms, and this has been afforded by the careful and extensive studies of Hayem, Birch-Hirshfeld, Leyden, Unruh, Steffen, Ribbert, Romberg, Councilman, Mallory and Pearce and many others. Though they differ in regard to certain unessential details, their agreement is general and striking. Moreover, Aschoff and Tawara, who on the basis of a critical study opposed many of the views in regard to the heart muscle in other diseases, state that the changes in diphtheria are extensive and severe. Thrombosis, endocarditis and pericarditis play only an occasional rôle. The two chief lesions are the parenchymatous and interstitial.

Fatty degeneration is extremely frequent. It varies in degree from an extremely mild to a marked change and it constantly accompanies the severer lesions. This degeneration may occur in the first few days, but it is also found late in the disease. A much more severe degeneration which affects all parts of the muscle fiber, the contractile elements, the protoplasm and the nucleus, and which leads to the formation of granular detritus and large irregular hyaline masses, is also found. This is both focal and general and is at times so extensive that it was estimated by Councilman that in one of his cases one-third of the heart was destroyed. This extreme degeneration is only found late in the course of the disease, rarely earlier than the seventh day.

The interstitial changes are of two types: In the one type there are focal collections of lymphoid and plasma cells. In the other there is an invasion of the degenerated and necrotic muscle cells with endothelial cells and polymorphonuclear leucocytes. The first of these types is usually accompanied by some degeneration of the myocardium, but it is not dependent on it, while in the second type, during the process of repair, an extensive formation of connective tissue may take place. It should be emphasized that the interstitial changes are essentially late changes. Up to the sixth or seventh day, then, fatty degeneration is practically the only abnormal condition present in the heart.

There has been no satisfactory investigation in regard to the intrinsic nerves and ganglia of the heart. The findings in the pneumogastric nerves will be considered later.

It is usually customary to divide the circulatory symptoms according to the time of their appearance into the early, or those occurring during the period of local lesions, which is usually febrile, and those occurring late or during the period of convalescence, which is almost always afebrile. This is not strictly correct, but is more satisfactory than dividing them according to their mode of production, which would take for granted things that are still sub judice.

EARLY CIRCULATORY DISTURBANCES.

The early circulatory disturbance occurring at the height of the disease is extraordinarily fatal. When fully developed it is practically never recovered from and but a few hours at most separate the beginning of the symptoms and the termination. Before the introduction of antitoxin it was greatly feared, and with reason; now, thanks to antitoxin, it is rarely seen. We meet it most frequently in older children or young adults in whom for several days the throat process has been neglected. The unfortunate patient presents all the evidences of malignant diphtheria. The process in the throat is extensive with membrane covering tonsils, uvula, soft palate, pharynx, sometimes extending into the larynx. The nasopharynx is filled with membrane, making nasal respiration impossible, and the upper lip is excoriated with the bloody purulent discharge which escapes from the nostrils. The cervical glands are greatly swollen so as to fill all the depressions in the neck and make a veritable collar around the throat.

The temperature is sometimes greatly elevated, at others little above normal, but the prostration is extreme and there is marked pallor. The heart's action is usually rapid, but the sounds are for a time of fair quality and the blood pressure is not much below normal. Before long, however, though sometimes after the local process in the throat has begun materially to improve, the pulse becomes weaker, the blood pressure falls rapidly and progressively, the heart's action becomes more and more feeble, and the patient quickly passes into a condition of collapse which is unaffected by cardiac drugs. The heart, however, continues in many cases to beat after respiration has ceased.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

The explanation that the death in these cases is a cardiac death failed to satisfy the critical. Naunyn, Harnach, Rosenbach and others objected to it on the clinical grounds that in the majority of instances the heart remains regular, it sounds clear, the pulse palpable until shortly before death, and that the increased frequency can not be looked on as a sign of cardiac weakness because, on the contrary, with extensive cardiac disease, as in the late stages of diphtheria, the heart may be slow.

Criticisms from the pathologic side were also not lacking. In many instances the changes found in the heart itself were entirely insufficient to account for death.

To explain these discrepancies Romberg and Pässler instituted their well-known experiments. These experiments were carried out on rabbits, before and during the stage of collapse, who had previously been injected with a large number of living diphtheria bacilli. Tests were made of the capacity of the heart to work against increased obstruction (compression of the aorta), and of the function of the vasomotor center as shown by its reaction to nasal faradization and asphyxia. Just before collapse the heart was capable but the vasomotor center slow and incomplete in its response. During collapse the vasomotor center failed utterly, while the heart was capable of beating with slightly diminished force if the stimulus of obstruction was provided.

The proof is undoubted and has been accepted save in regard to the condition of the heart. Romberg and Pässler considered this normal. Pässler and Rolly, some years later, continued the experiments, using more exact methods, and decided that while death was due to the paralysis of the vasomotor center, the heart undoubtedly was considerably affected.

There can be no doubt that these results explain satisfactorily the symptoms as we see them in man, and the circulatory phenomena are strikingly similar if due allowance is made for the fact that in man the toxin is slowly absorbed through a period of many hours, and in animals, for technical reasons, it must be given in enormous doses at one injection. The fact that the heart shows impairment even without anatomic change gives some foundation for Hesse's theory of a functional interference with its action, due to the effect of the toxin, even though this has been vigorously denied by many writers on the subject.

Romberg's and Pässler's results have been generally accepted, but, curiously enough, not made use of by those writing on the therapy of this condition. Pässler investigated the effects of drugs on experimental animals. Caffein, camphor and digitalis, in the order named, were of most value, and infusion of salt solution had a favorable effect. But all the improvement was only temporary. This is only to be expected in view of the enormous quantity of toxin that was used.

In man it is interesting to speculate if, with poisoning so severe as to affect the vasomotor center, recovery is ever possible. One may imagine a condition where the balance was so slight on the wrong side that survival for a few hours might turn the scale toward recovery. No matter how unfavorable the outlook, we should use all our efforts, but they should be intelligently directed.

Caffein, camphor and digitalis hypodermatically and frequently repeated for their effect on the center, and adrenalin for its constricting influence on the blood vessels, are indicated. The last is so evanescent that but little can be hoped from it. Its use is, however, theoretically correct. One or two infusions of salt solution may be used. From antitoxin at this late date we can expect nothing. It should have been used long before and in sufficient quantities.

LATE CIRCULATORY DISTURBANCES.

The late circulatory disturbances may appear at any time from the second to the fifth week or even later. It seems unnecessary to adopt Förster's elaborate classification in regard to them, but he has shown that the time of their appearance has an important bearing on the prognosis.

We meet these disturbances usually in older children, and in the majority of instances after severe infections which have been untreated for a considerable length of time, but it is astonishing to see after how mild a local infection trouble with the myocardium may occur. It is only in uncomplicated cases that symptoms may be studied properly. Pneumonia and other complications so disturb the picture that it is at times impossible to recognize the condition.

We may divide the symptoms into those presented by the pulse and heart and directly dependent on the circulation, and those of a more general character. Many of those presented by the heart and pulse are easy to elicit, while others depend more or less on the personal factor of the examining physician, and there is a great discrepancy in opinion regarding them which more or less destroys their statistical value.

The first symptoms are usually found between the ninth and fifteenth day, whereas anatomically the late changes, i. e., necrosis and hyalin degeneration and interstitial infiltration, may be found from the sixth to the ninth day. This, taken with the fact that at autopsy there may be found considerable myocardial change that in spite of the most careful examination has escaped clinical observation, demonstrates that the pathologic changes require several days development before they are sufficiently marked to give recognizable symptoms.

The first symptoms are usually found in the pulse, which drops with the temperature, often to below normal, and may remain there for several days before rising again, or it may rise and fall again and repeat this several times. In a certain percentage of cases it may stay persistently high. Either of these actions means almost certainly myocarditis.

At other times the first symptom is irregularity in force or rhythm of the pulse. Irregularity in force is much more important than that in rhythm, for the latter is frequently encountered in children, while, on the other hand, the pulse may be regular throughout the course of a severe myocarditis. Irregularity in force, however, is constantly present and may remain for months. The pulse, though it may be regular, is very unstable, is affected by the emotions and by exercise to a most pronounced degree and may retain this quality far on into convalescence when all other evidences of disease have disappeared. As before mentioned, the rapidity varies greatly and from it alone not much information can be obtained: the worst prognosis is to be given those cases with a low and constantly falling rate.

An examination of the heart reveals the same abnormalities as does the pulse, but in addition others on which much attention has been focused, and foremost among these are murmurs and evidences of dilatation.

It is with regard to these two that the personal factor of the examining individual plays such an important part, and it is therefore no surprise to find that the interpretation of results by different observers varies widely. It is universally agreed that murmurs are frequently present at this time; they are in the vast majority of cases systolic in time, blowing in character, and though at first heard loudest over the base or body of the heart, eventually are heard with greatest intensity in the vicinity of the apex. It is also universally agreed that endocarditis is very rare. There is a great diversity of opinion in regard to the meaning of these murmurs. Hibbard considered that 10 per cent. of diphtheria patients had evidences of actual regurgitation through the mitral valve, while White and Smith, working in the same hospital some years later, considered that 75 per cent. of their patients leaving the hospital had murmurs thought to be organic and due to mitral insufficiency resulting from changes in the heart muscle. There is almost as great a difference of opinion among other observers. While there is undoubted evidence that murmurs from dilatation occur and occur frequently, it seems to me that the value of these murmurs as an index of mitral insufficiency due to dilatation has been greatly overrated, and that we should look on them with some caution.

Whether or not we accept Sahli's views as to the production of accidental murmurs, we have present in diphtheria those conditions in which they are usually found, that is, dilated blood vessels and an anemia marked and progressive. Hochsinger's assertion that accidental murmurs are unusual in children is true only of the very young, and the circulatory disturbances are usually met with in the older. Then, too, murmurs appear and persist only a few hours or days, and may disappear and even reappear again. This could hardly be true were they due to organic muscular lesions. Mallory's findings in one case of changes limited to the papillary muscles alone suggests the part that they may play. An accentuation of the second pulmonic sound as an evidence of regurgitation should also be regarded with caution as a second pulmonic sound louder than the second aortic is the rule up to adult life, and the accentuation may be only relative on account of the great weakness of the first sound. Finally, so many patients with these auscultatory changes show nothing else abnormal that it is difficult to reconcile the mildness of the clinical course with the assumed severity of the anatomic lesion.

Murmurs are seldom the only symptom, but, on the other hand, there may be a fatal termination and no murmur at any time. For these reasons we can not draw accurate deductions as to the severity of the lesion present from the presence or absence of these murmurs.

In regard to dilatation there is equally a difference of opinion. Unruh thought that the dilatation was usually of the right side of the heart; Schmaltz, Förster and the majority of observers think it occurs chiefly on the left side. Förster, however, says that it is frequent on the right side with croup. Rabot and Philippe believe the diagnosis of this condition to be so difficult, especially in children, as to render the results untrustworthy. It is my personal opinion that dilatation has been diagnosticated too frequently, but it would, nevertheless, be quite incorrect to pretend that it is a rare or unusual condition.

EVIDENCE OF MYOCARDIAL DISEASE.

As an evidence of myocardial disease there is another sign which is of greater value than any of the others on account of its great constancy. This is the alteration in the character of the first sound of the heart. No murmurs or evidences of dilatation may be present even in fatal cases, the pulse may be regular in rate and normal in rapidity, but the first heart sound betrays the difficulty. The alteration consists in the more or less complete disappearance of the muscular element in the first sound, the valvular element remaining, or this also may be diminished and even absent. This makes the first sound short, weak, and, as it is usually described, "valvular" in quality. At times the loss of muscular quality is so marked that only by the length of diastole can we tell which is the first and which is the second sound, and if, as sometimes occurs, the pause between the first and second and the second and the succeeding first sound are of equal length, and the so-called "embryocardia" results, this may be impossible. This is no new observation; it was long ago noticed, and is usually mentioned, but never the emphasis laid on it that it deserves.

The absence of a normal sound or element of a sound is exactly as important as the presence of an abnormal one, though not so apt to attract attention. The change is not always easy of recognition, for which frequent examinations by an experienced person are required. A moment's consideration, however, points toward this as the logical abnormality to be found. The great dependence of the first sound on the muscular contraction for its quality, and the anatomic changes present in and around the muscle fibers in diphtheria, clearly demonstrate why this change in quality takes place. I have been struck with the constancy of this sign and its great persistence, lasting as it does at times for weeks and months, even after murmurs accompanying it have disappeared.

Its value may also be demonstrated by means of a test such as Gräupner's. I have made a few of these, enough to satisfy myself of the truth of this statement. Gräupner's test, as you know, is the testing of the pulse rate and blood pressure before and after a certain amount of physical exercise. The normal or compensated heart reacts to this by a rapid rise in pulse rate, which in the course of a very few minutes returns again to normal and by a more gradual rise in blood pressure which persists for a considerable length of time after the rate is normal. Insufficient hearts react in various ways, such as by a failure in pressure rise or a persistence of increased rate.

It is, of course, necessary to perform this test with great care; therefore, in the case of the boy of 9 years whose chart is here shown, instead of having him perform several thousand foot pounds of work, as is usually done, I only allowed him to run up a few steps, amounting to 783 foot pounds of work. He was a boy who had had a moderately severe diphtheria untreated for five days three weeks before. When I made the first few tests he had a weak, valvular first sound at the apex and a faint systolic murmur. The chart shows his failure to react to this test; his pulse rate rose and sank shortly, but the blood pressure, instead of rising, fell and remained subnormal for eighty-seven minutes. Seventeen days later, when the first sound of his heart was again normal, he reacted, as the chart shows, quite normally. An increased amount of exercise would undoubtedly have made the changes still more striking, but I did not consider it safe. It is, therefore, much better to depend on the first sound of the heart as an index of the patient's ability to be allowed to take exercise rather than on the presence and absence of murmurs.

Studies in regard to the blood pressure are incomplete and unsatisfactory. The pressure may remain fairly high though generally somewhat below normal. A pressure below 75 mm. always indicates a serious condition and below 70 mm. a very dangerous one. Patients showing a progressive fall should excite the most concern.

Dyspnea, precordial distress, cyanosis, edema and evidences of passive congestion are rare, except passive congestion of the liver, the presence of which is in striking contrast to the absence of congestion elsewhere. Congestion of the liver causes an increase in hepatic dulness, marked tenderness and sometimes pain in that organ.

The general symptoms are at times very much in evidence. One of the earliest of these is pallor, which is found before there is sufficient anemia to account for its great development. A child whose color one afternoon presents nothing abnormal, on the following day may be blanched with an almost cadaveric pallor. Children also may show pronounced mental symptoms, being either apathetic, somnolent and indifferent, or at times excitable, restless and irritable. Gastrointestinal disturbances, especially vomiting, may be present. The vomiting may occur at any time in the course of the disease, may be persistent, and when severe always excites concern. Schmaltz says that it is not probable that these conditions are always the consequence of circulatory disturbances, and that they not infrequently come on at a time when this explanation hardly seems to be supported by the condition of the heart. Loss of weight is also common even during convalescence, when there is no fever and when patients are ingesting a perfectly satisfactory amount of food. I wish to discuss later these symptoms somewhat more particularly.

CAUSE OF DEATH.

The cause of death has not been worked out experimentally. Hallwachs attempted it ten years ago, following the method of Romberg and Pässler, but did not use toxin and was unable to produce post-infectious circulatory disturbance with characteristic changes in the heart muscle. There are great difficulties in accomplishing this, but there is every reason why it should be done. Clinical evidence, though, is conclusive in regard to myocarditis as the cause. Krehl expresses the general view when he says that the circulatory disturbances in convalescence are undoubtedly due to myocarditis; both processes run parallel, and it is clear from the development and exhibition of symptoms that they are to be referred to an insufficient heart muscle.

Henoch, Strümpell and others have sought to explain certain symptoms on the basis of disturbance with the cardiac ganglia, but, as Romberg says, it does not seem necessary to bring in factors which are so slightly understood when there are sufficient explanations in the muscle itself.

TREATMENT.

As far as treatment is concerned there can be no doubt that rest and general management accomplish much more than drugs. All are agreed as to this. On the subject of the value of the different circulatory stimulants there is far less unanimity of opinion. The number of drugs that have been advised in this condition is proof of their inefficiency, especially when practically all observers agree that digitalis, the most certain of all cardiac stimulants, fails in its effect. This at once raises the interesting question whether, if the cardiac muscle is so extensively diseased as to fail to meet the demands made on it by its normal regulatory apparatus, it is capable of being advantageously stimulated by drugs. Clinical experience seems to indicate that it is not, and if occasionally a clinician speaks favorably of one drug it has always been found ineffective in the hands of others. Krehl frankly states that drugs are unsatisfactory. Certainly we can expect very little permanent effect from their use and permanency of effect is what is required, for the myocardial lesions require days and weeks and not hours for their cure.

PNEUMOGASTRIC PARALYSIS.

I have left until the last, because I wish especially to consider that interesting and extremely fatal type of case, usually ascribed to pneumogastric paralysis. The picture of this condition is well known and justly dreaded. It occurs generally after a severe infection untreated with antitoxin or treated late. After a subsidence of the local symptoms convalescence apparently begins, but in my experience careful observation has never failed to show evidence of circulatory disturbance and myocarditis. This disturbance frequently increases in severity, and with it often appear together the three symptoms on account of which the pneumogastric nerve is accused. These are slow pulse, epigastric pain and vomiting. Within a short time the patient goes into a condition of most profound collapse and often is comatose just before the end. To explain this striking symptom-complex it has been the habit to invoke changes in the pneumogastric nerves, especially as these nerves examined postmortem in a number of fatal cases following such symptoms have shown degenerative lesions.

Now to prove the involvement of the pneumogastric nerve, this nerve must be found degenerated in all such cases and, per contra, undegenerated in practically all others. Huguenin, Leyden and other early observers who examined these nerves pronounced them generally normal, but with the modern technic and care the results have been far different. Thus in a series of nine cases reported by Hibbard, fifteen by Thomas, two by Steensland, twenty-eight by Mallory and fourteen by Thomas and Hibbard, a total of sixty-eight in all, the pneumogastric nerve was found to be degenerated in every single case. These changes were found without regard to the association of symptoms, some had vomiting, some pain and some slow pulse; others had none of these, and in many the diphtheria was very mild, the fatal outcome being referred to a complicating scarlet fever or measles which supervened on the original diphtheria infection. Moreover, in an 11-months-old child dying of pneumonia, definitely not due to diphtheria, who had shown none of these symptoms, Thomas found an extensive degeneration of the nerve.

These findings almost completely dispose of the pneumogastric nerve as a factor in producing the symptoms that have been referred to it, otherwise we should meet this symptom-complex daily. Nor can, in some cases at least, the slow pulse be referred to the vagus. Bradycardia occurs following typhoid and other infectious diseases as well as diphtheria, and Dehio found that this bradycardia was unaffected by atropin. Schmaltz made the same observation in diphtheria. Atropin by its effect on the vagus termination prevents its inhibitory effect on the heart, and were the slow pulse due to the vagus, after the use of atropin in sufficient quantity, the rapidity of the heart would be greatly increased. But this has not been found to be the case. Theoretically also we should expect a rapid and not a slow pulse with an extremely degenerated vagus.

It seems to me that we can best consider the vomiting in connection with some of the other symptoms that occur in the period of apparent convalescence. These are the pallor, great prostration, progressive emaciation, stupor and at times convulsions. In regard to them no explanation is usually vouchsafed.

It is known that the toxin of diphtheria is very quickly fastened to the cells of the body; that the combination is at first loose and can be broken up by antitoxin, but that after a few hours the toxin can no longer be dislodged from the cells. Yet its effect is not at once manifest. For instance, nephritis may develop late, myocarditis at times does not appear for weeks, and peripheral neuritis may not be manifest for months. But the toxin is none the less powerful, as its profound effect on almost all the body tissues shows, and prominent among these effects are the great changes in the liver (extreme degeneration and necrosis).

With a knowledge of these facts I have begun a study of the metabolism of diphtheria, which has been singularly neglected. I can find no reference to this work in man, and only two very incomplete studies in animals by De Croly and Noel Paton. De Croly found in rabbits an increased nitrogen excretion which was of short duration, and Paton, who was investigating the effect of fever, found an increase in nitrogenous metabolism in dogs.

I only wish to show at the present time the nitrogenous excretion during two days in the case of a boy 15 years old who had a severe process in the pharynx and who was ill three days before being treated with antitoxin. His throat cleared up rapidly, his temperature fell to normal and his pulse to below normal. He suffered for two weeks from evidences of myocarditis, but thereafter improved rapidly and was discharged cured.

His urine was collected for twenty-four hours, beginning twenty-four hours after his temperature reached normal. This was done so as to eliminate the influence of fever on nitrogenous excretion. The urine was again examined eight days later. On each of these two days he took only a milk diet.

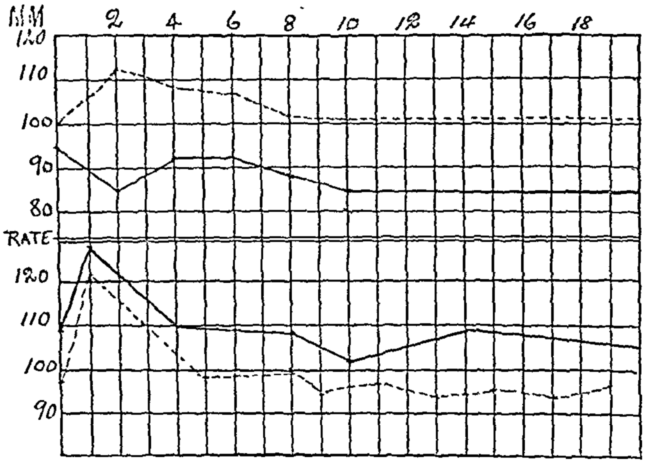
gms. and excreted only 10. The extraordinary excess of the excreted nitrogen on the first day is at once a striking feature; there is nothing abnormal that can be

It will be seen by the table that during the first day he ingested a little over 9 gms. of nitrogen and excreted over 24, while eight days later he ingested 13

made out in the proportion of the different nitrogen-containing substances. This great excretion of nitrogen, however, is evidence of some marked influence which in the absence of fever or other disturbing factor we must refer to the latent effect of the toxin. Extensive studies are required on this aspect of the question, but I feel sure that we shall find, especially in fatal cases, and most of all in those with marked liver and kidney changes, evidences of great metabolic disturbance. In this way, it seems to me, the general symptoms and the vomiting can be best explained, referring the slow heart and other circulatory symptoms to the concomitant myocarditis.

Day.	Nitrogen of food.	Nitrogen of urine.	Urea, N.	NH_3 N.	Creatinin N.	Creatin N.	Uric acid N.	Undetermined N.
7	9.0+	24.14	19.19	1.65	0.43	0.33	0.24	2.3
			79.4	*6.9*	*1.8*	*1.3*	*1.0*	*9.5*
15	12.0+	10.06	8.18	0.73	0.30	0.12	0.11	0.62
			81.3	*7.2*	*3.0*	*1.2*	*1.0*	*6.3*

The table shows the excretion of nitrogen (in grams) during the seventh and fifteenth day of illness. The figures in italics are the percentages of total nitrogen. The great excretion of urinary nitrogen on the seventh day is striking. The temperature was normal on both days.



The chart shows the reaction after exercise when the first heart sound was abnormal (solid line) and when, seventeen days later, it was normal (broken line). It will be noticed that when the sound was abnormal the blood pressure fell and remained low, whereas seventeen days later it rose promptly after exercise.

STUDIES IN INFANTILE DIGESTION.*

ALFRED FRIEDLANDER, M.D.
CINCINNATI.

The problems of digestion in infancy and early childhood have engaged the attention of pediatricians for a long time, and our literature is filled with discussions as to the digestive activities, possibilities and difficulties in early life. A method of study which approaches the subject from a new view-point should, therefore, have a certain justification. It seemed to me that the bead test, as originally devised by Einhorn, might be a valuable method of direct clinical study. This test was proposed originally for adults, but the feasibility of its use for children struck me. Once engaged on the study of this test, the possibility of its application to very young children, indeed to new-born infants, was apparent, provided that certain difficulties of technic could be overcome. By the procedure about to be described, it was found to be very easy to apply the test to infants of any age. A systematic trial of the test was therefore undertaken to determine its value as a working method in infants and children.

THE BEAD TEST.

Einhorn's method, briefly, is as follows: Small pieces of various food stuffs are fastened to small glass beads by a silk thread. The beads are strung together by an additional thread and the string of beads, with attached food stuffs, is put into small gelatine capsules. These capsules are swallowed by the patient and the string of beads is then later recovered from the stool. The exact time required for the passage of the beads through the gastrointestinal canal must be noted in each instance. If the beads remain in the tract over fifty hours, the results are not considered reliable, because of the possibility of degeneration as the result of the action of the intestinal bacteria.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Einhorn has recommended the following test substances:

Mutton fat, for fat digestion. Beads are dropped into melted mutton fat, which is then allowed to cool, so that the beads become coated with the fat.

Beef, for proteid digestion. Small strands of raw fresh beef or of raw beef in alcohol are tied to the beads.

Potato, for starch digestion. Potatoes are boiled for two minutes, and small pieces cut with peel attached. These pieces are sewed to the beads.

Catgut, for fibrin digestion. Small strands of raw catgut are tied to the beads.

Nuclear digestion, small pieces of sweetbread. These are enclosed in small gauze bags and the bags are tied to the bead. After the passage of the bead with the sweetbread, the bag is opened, contents, if present, cleaned, smears made on slides and stained with methylene blue and examined to see whether nuclei are still present. It is not considered as absolutely proved that the presence of nuclei in the sweetbread substance after passage through the intestinal tract must necessarily indicate the absence of active trypsin, but, on the other hand, if the nuclei are all digested, it is safe to conclude that active trypsin is present.

AUTHOR'S EXPERIMENTS.

The present series of experiments was conducted on two lines. Older children, able to swallow capsules, were given capsules prepared according to the method of Einhorn, with one modification. This was, that in my series, all of the food stuffs were enclosed in small bags of wide meshed gauze so as to eliminate the possibility of error from the tearing loose of the food stuffs from the bead. It was found to be perfectly feasible to have five small bags containing mutton fat, catgut, potato, beef and sweetbread, each attached to a special colored bead (for purposes of identification), all inserted into a five grain capsule, which the older children had no difficulty in swallowing.

For very young children and infants, the following modification of the method was devised. Naturally, the swallowing of capsules would be out of the question in the case of infants, and several infants in the series to be reported were less than one month of age at the time of experiment. Single beads each with a single food stuff in attached gauze bag were used. By means of a small piece of rubber catheter the introduction of the food stuff into the infant's stomach was comparatively easy. The bead was inserted into the end of the previously sterilized piece of catheter. The catheter was pushed past the constrictors of the pharynx as in the introduction of a stomach tube, and then by means of a stilet passed through the catheter, the bead was pushed out of the catheter and thus into the esophagus. After some little experiment I found that an olive pointed Otis bougie answered very well as a stilet. No difficulty was ever experienced in the introduction of the beads into the esophagus. Indeed, there could be none, as there is no danger of the beads getting into the larynx.

The introduction of the beads was found to be surprisingly easy, even in the case of infants only a week old. Nor did any bad results ever follow the introduction of the beads, though the complete list of experiments on infants and children included over two hundred different administrations. The recovery of the beads from the stools was also very simple, and in a hospital, with careful supervision of the children day and night, the exact time required for passage could also be noted in every case.

The results of the experiments are tabulated in Tables 1-9.

Three experiments. All +. Children aged 10 weeks, 9 months, 13 months. (+ = digestion. p = partial digestion (at least half). — = no digestion.)

SUMMARY.

CAPSULE SERIES.

In only one child, a boy of 11 (with tubercular knee), was there complete digestion of all the food stuffs, and this complete digestion occurred twice in this child. The sweetbread was digested completely in all cases. The mutton fat was completely digested in 21 out of 25 experiments. The catgut was digested 17 times, the raw beef 14 times and the potato only 8 times. In both the raw beef and potato series partial digestion was noted in a considerable number of the cases where there was no complete digestion.

Placed in the order of their positive results, these capsule experiments showed the following order for the digestibility of the different food stuffs: Sweetbread, mutton fat, catgut, raw beef and potato. It is noteworthy that there was complete digestion of the sweetbread in every case, as evidence of the activity of the trypsin, while the starch digestion was least active. Practically similar results were obtained in the infants with single beads.

The average time required for the passage of the capsule in the 25 experiments was 22⅓ hours, with 32 and 17 hours as the extremes on either side.

SINGLE BEAD SUMMARIES.

Raw Beef.—Forty-one experiments. In children over 1 year, there were 25 experiments; 14 showed complete digestion; 5 showed partial digestion. In children under 1 year there were 13 experiments, with 5 complete and 2 partial digestions. In 2 children, each aged 5 months, there was complete digestion.

Milk Curd.—Twelve experiments in children varying in age from 5 weeks to 12 months, complete digestion in every case.

TABLE 2.

Raw Beef.—In first experiments a single strand was tied to the bead. In most of the experiments a small mass of raw scraped beef was placed in a wide meshed gauze bag and tied to the bead.

Sweetbread.—The sweetbread experiments numbered 28. Twenty showed complete digestion. 6 partial and 2 no digestion. One of the negative cases occurred in a 12 months old baby and the bead passed in 8½ hours, so that the very rapid passage might easily explain the lack of digestion. The other negative case occurred in a child of 10 weeks, who on four other occasions did digest the sweetbread. And even on the occasion when the sweetbread substance was not digested. the nuclei were completely digested. In order to test nuclear digestion.

in other words, to study the activity of trypsin at a very early period of life, a special series of sweetbread experiments was undertaken in children of very young age. In this series there were 13 experiments, the children ranging in age from 5 months to 8 days. In these cases microscopic smears were made after the sweetbread beads had passed. The bags were washed, then opened, smears made of the residue, and the smears stained with methylene blue. In none of the cases were any nuclei to be found, even when there was some sweetbread residue left. Inasmuch as it is now settled that nuclear digestion as such occurs only as the result of pancreatic activity (trypsin) it seems proved that the pancreas must be functionally active from birth. It is of special interest to note that in a child of 8 days, there should have been complete digestion of the sweetbread.

Potato.—The series included 27 experiments. All of the children, except three, were less than 16 months old. There was complete digestion 5 times, partial digestion 6 times, and no digestion in 16 cases. This comparative inability to digest the starches was, of course, to have been expected and was in direct line with the potato experiments in the older children.

This series of experiments was undertaken primarily to test the method, more especially to try the method for infants. Sweeping conclusions are, of course, quite out of place, as the result of what is after all a limited number of observations. It would seem, however, that the method bids fair to be an addition of value as a means of studying digestive processes in infancy and early childhood. It is, at least, possible that by this method some light may be shed on the physiology of the digestive processes in infancy. The results of the experiments with sweetbread, with special reference to nuclear digestion and the proof thereby afforded of pancreatic activity from birth, are certainly suggestive. A profitable field of inquiry may thus be opened. On the other hand, from the clinical standpoint, the test may prove valuable in infancy. In a given case of malassimilation the test may afford an index as to the special form of food stuffs whose digestion is imperfect and a way thus be afforded of determining a rational alimentary therapy for the individual child.

The report here offered is to be considered as a preliminary study merely, and it is hoped that special phases of the many questions of digestion in infancy may, by this method, now be studied in detail.

4 West Seventh Street.

ABSTRACT OF DISCUSSION.

Dr. J. P. Sedgwick, Minneapolis: We know that there is a difference in the digestion of mutton fat and the fat which the infant gets normally, that is, emulsified fat. It has been shown that the digestion of fat in the stomach does not occur on using this very fat which the doctor has used, and it gave us the impression for many years that fat is not digested in the stomach. The later work of Volhard with emulsified fat shows that it can be digested in the stomach. He worked with an emulsified fat of the egg yolk. Dr. Friedlander's own work shows us the difference between the digestive power of the infant on the mutton fat and the emulsified fat of the egg yolk which he found, I believe, digested in practically every case. Therefore, it would seem that in the routine work the yolk fat would be more applicable than the mutton tallow which has been suggested.

Dr. A. W. Fairbanks, Boston: There has been in some parts of the south a tendency to use potato in the feeding of infants. I think that the results of Dr. Friedlander's experiments should effectually and permanently dispose of any such idea.

Dr. Alfred Friedlander, Cincinnati: These experiments were not offered as conclusive. I wanted to know whether it would be possible to employ this method in feeding infants. As to the criticism in regard to mutton fat, it is thoroughly justified. I simply explain that these results are not to be considered as proof of anything definite as to digestibility of fat. Special detailed studies concerning fat and starch digestion are now to be taken up, inasmuch as it is proved that the method is applicable to and valuable for the study of infantile digestion.

PHYSIOLOGIC ASSAY OF NITROGLYCERIN TABLETS, DIGITALIN TABLETS AND FLUIDEXTRACT OF ERGOT.*

CHARLES WALLIS EDMUNDS, M.D.
Professor of Materia Medica and Therapeutics in the University of Michigan.
AND
GEORGE B. ROTH, A.B.
ANN ARBOR, MICH.

Last year in the pharmacologic laboratory of the University of Michigan we undertook an examination of various preparations of such drugs as were suitable for physiologic assay. The object of the examination was to ascertain the relative strength of such medicines when prepared by different manufacturers, some of whom assayed their products physiologically while others relied entirely for an active product on their efforts to purchase the best crude drugs on the market.

The examinations naturally began with the heart tonics, digitalis and strophanthus, because of their great importance and also because there exists a good method by which they can be assayed. The results[1] showed that various preparations of the tincture of digitalis varied in strength in the ratio of 1 to 4, that is, some were one-quarter the strength of others, with still others representing all intermediate gradations, while tinctures of strophanthus showed practically the same variations. Recently other drugs have been examined in the laboratory, and those especially taken up were nitroglycerin tablets, digitalin tablets and ergot.

Nitroglycerin tablets were examined both in respect to the relative strengths of different makes and also with regard to the effect of age on them. These were especially selected for examination as there exists at the present time a widespread feeling of distrust regarding the efficiency of these tablets and the length of time that they will retain their medicinal properties. With this object in view we obtained seventeen different preparations of nitroglycerin hypodermic and compressed tablets, representing seven of the leading manufacturing drug houses in the country. These were examined in February and again in May, 1908.

This period of four months we realize is entirely too short to allow any definite conclusions to be drawn as to the effect of age on the preparations, but through the kindness of the individual manufacturers we have been able to obtain from them the date of manufacture of all these specimens showing that some of the tablets were made as long ago as 1901.

The method of examination we adopted was to observe the effect on the blood pressure of a rabbit when the drug was injected into the circulation in very small doses. This method, while perhaps not strictly accurate, gives a very fair idea as to whether or not the drug is active and its approximate strength. The rabbit is prepared as for any blood-pressure experiment. After complete anesthesia is produced by the administration of paraldehyd a cannula is inserted in the jugular vein to permit of the injection of the drug, and in the carotid artery is another cannula tied which is connected with the ordinary mercury manometer, the connecting system of tubing being filled with sodium sulphate solution to prevent coagulation of the blood.

---

* Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

[1] Edmunds: The Journal A. M. A., May 25, 1907, p. 1744.

RELATIVE STRENGTHS OF DIFFERENT MAKES.

By a series of trials we found that minute doses were sufficient to produce a definite fall in blood pressure. We finally adopted 1/4,000 grain and 1/2,000 grain doses, using the one as a check on the other. To obtain these amounts a 1/100 grain tablet of nitroglycerin was dissolved in 40 c.c. of physiologic salt solution; 1 c.c. of this solution with 1 c.c. of salt solution represented 1/4,000 grain of nitroglycerin, while 2 c.c. of the solution contained 1/2,000 grain. In this way the same amount of fluid was injected at each trial and so far as possible the injections were made at the same rate.

Each preparation was assayed on several rabbits until some sort of uniformity was obtained as to the percentage of fall in pressure which it would produce when given in the doses named. These percentages were then averaged and the results are given in the following table, in which the different preparations are arranged according to age as determined by the dates furnished by the makers:

Dose of Nitroglycerin and Percentage Fall in Blood Pressure.

	Date of Manufacture.	1/4000 gr.	1/2000 gr.
1.	December, 1901.......	27 per cent.	32 per cent.
2.	December, 1901......	28 per cent.	36 per cent.
3.	——— 1905?.........	17 per cent.	22 per cent.
4.	——— 1905?.........	22 per cent.	32 per cent.
5.	October, 1905..........	20 per cent.	28 per cent.
6.	January, 1906..........	34 per cent.	45 per cent.
7.	April, 1906............	19 per cent.	28 per cent.
8.	September, 1906.......	31 per cent.	53 per cent.
9.	March, 1907...........	35 per cent.	42 per cent.
10.	April, 1907............	19 per cent.	31 per cent.
11.	April, 1907............	19 per cent.	29 per cent.
12.	May, 1907............	28 per cent.	40 per cent.
13.	July, 1907............	29 per cent.	36 per cent.
14.	August, 1907.........	23 per cent.	30 per cent.
15.	September, 1907.......	18 per cent.	27 per cent.
16.	October, 1907.........	26 per cent.	31 per cent.
17.	November, 1907.......	29 per cent.	36 per cent.

This table shows that the so-called 1/100 grain tablet when injected in 1/4,000 grain doses lowers the blood pressure on an average about 25 per cent. and in 1/2,000 grain doses about 34 per cent. Some of the preparations, however, show rather wide variations, as, for instance, Nos. 3, 6 and 9, but, on the other hand, with a certain number the results are uniform. This uniformity is well shown in four samples made by one firm. These gave percentages as follows:

No.	1/4000 gr.	1/2000 gr.
5..............	20 per cent.	28 per cent.
7..............	19 per cent.	28 per cent.
10..............	19 per cent.	31 per cent.
14..............	23 per cent.	30 per cent.

It is true that these are all weaker than the average.

To get some clearer ideas as to what these different percentages indicate in regard to the relative strength further dilutions of the solution to be tested were made, and these in one of the experiments gave the following percentage results:

1/16,000 gr.	1/8,000 gr.	1/4,000 gr.	1/2,000 gr.
11 per cent.	14 per cent.	20 per cent.	27 per cent.

In this experiment two-thirds of the total number of tablets tested varied only from 2 to 4 per cent. from these figures when given in the corresponding doses. One, however, gave a fall of only 10 per cent. from 1/4,000 grain dose, and 12 per cent. from 1/2,000 grain. This would indicate that this preparation was certainly less than one-quarter of the strength of the solution against which it was measured, which in turn itself was not up to the average, giving 20 per cent. and 27 per cent. drops in pressure from the 1/4,000 grain and 1/2,000 grain, whereas the average, as mentioned earlier, was 25 per cent. and 34 per cent., respectively.

Also in this experiment there was one preparation which, administered in 1/2,000 grain dose, gave a fall of 37 per cent. in the pressure, indicating much greater strength. This same specimen administered to another animal gave the following results:

1/16,000 gr.	1/8,000 gr.	1/4,000 gr.	1/2,000 gr.
20 per cent.	25 per cent.	29 per cent.	38 per cent.

These percentages would appear to indicate a very much stronger tablet, in fact, from two to four times as strong as the first tablet when judged by corresponding dilutions. But it is very hard to carry over results in one experiment to another for an exact comparison, as the animals differ somewhat in susceptibility to the drug, one giving a uniformly greater reaction than another. But comparing the various tests on the same animal usually shows that the individual specimen which produced the greatest depression in one test also gave the best result in a second animal and *vice versa.*

A study of all the results we have obtained in the various animals, and of the averages which we give in the table, leads us to conclude that the nitroglycerin tablets hardly deserve the bad reputation which has been given them. It is true they vary considerably in strength, but of the seventeen specimens examined we think only two (Nos. 3 and 15) should be classed as distinctly poor. Next to these two come the great majority of the preparations, and a comparison of these with the percentage attained by giving the drug in the more minute doses of 1/16,000 and 1/8,000 grain indicates that they vary even as much as 100 per cent., some being half the strength of others. Two samples (Nos. 6 and 9) were considerably stronger than the average. Our results certainly confirm the view very generally held as to the variability in the strength of these tablets, but show that the opinion frequently expressed that these tablets are worthless is incorrect.

EFFECT OF AGE ON NITROGLYCERIN TABLETS.

We have had very largely to base our conclusions as to the effect of age on the tablets on the dates furnished us by the makers. Taking the table given earlier, we have grouped the tablets by the years in which they were made and averaged the results.

Effect of Age on Nitroglycerin Tablets.

Date of manufacture.	No. of specimens.	1/4,000 gr.	1/2,000 gr.
1901	2	28 per cent.	34 per cent.
1905	2	20 per cent.	27 per cent.
1906	3	28 per cent.	42 per cent.
1907, *1st* 6 *mos.*	4	25 per cent.	36 per cent.
1907, 2d 6 mos.	5	25 per cent.	32 per cent.

This table would indicate that there was no marked deterioration in the tablets due to their age, a conclusion which is contrary to the general opinion. As a control to the 1901 specimens (which were both made by one firm) we tested some tablets which one of us had had in his possession since July, 1902, and during this time they had been kept in a cool dark place in a tightly-corked bottle. One of these tablets was as active as any preparation we tested, but several others which we used proved to be absolutely inert. Leaving, then, the two 1901 specimens in the list out of consideration, the table still shows that the 1905 tablets were weaker than those made more recently, but the 1906 specimens show up very well.

Another check as to the effect of time on them was obtained by comparing the results of the experiments carried out in February, 1908, with those performed in May. An average of all the readings obtained during these two series of experiments is as follows:

	1/4,000 gr.	1/2,000 gr.
February, 1908	23 per cent.	36 per cent.
May, 1908	25 per cent.	32 per cent.

The figures are so nearly alike that they may be said to balance one another. Any conclusion based on these findings must be drawn very cautiously, but it would seem perfectly safe to say that tablets which are not more than two years old have lost practically none of their strength, but that if they are older than that they have probably deteriorated to a greater or less extent.

DIGITALIN TABLETS.

Another drug which in tablet form is very commonly employed in practice is the so-called digitalin. Under this name Merck lists three preparations: the "German," which is said to consist of digitalin (Kiliani), digitonin and digitalein; "French," an amorphous glucosid, which is practically insoluble in water; and "crystallized" digitalin, which is without action on the heart. The preparation used in these tablets is probably the "German," as the tablets are freely soluble in water. A hypodermic preparation of the digitalis group would be of very great use if it could be relied on in cases of emergency in which the preparation of the crude drug could not be used. In many cases in which we have used tablets, however, these have seemed to have so little effect that we secured a number of 1/100 grain and 1/50 grain tablets and assayed them. The method we employed was to test their effect on the frog's heart in a similar manner to that described in our paper on digitalis assay.[1]

The following doses indicate the amount necessary to bring the heart of a 20 gm. frog to a systolic standstill in one hour:

Five specimens took 1/20 grain (five 1/100 gr. tablets).
Four specimens took 1/25 grain (four 1/100 gr. tablets).
One specimen took 1/30 grain.

These figures become more significant when we consider that in our assay of the tincture of digitalis we found that an average preparation would stop the frog's heart in systole in one hour when administered in from 0.15 c.c. to 0.20 c.c. The immediate conclusion to be drawn is that digitalin is administered to man in entirely too minute doses. If on the frog 1/25 grain of digitalin equals 0.2 c.c. tincture of digitalis, then the corresponding dose for man should be 5/25 grain (1/5 gr.) instead of 1/100 or 1/50 grain.

This seemed such a very large dose compared with that in common use that we decided to test this ratio on dogs. We, therefore, prepared dogs in the ordinary way to take tracings from a heart with the myocardiograph and into the first we injected four 1/100 grain digitalin tablets which had been dissolved in salt solution. An analysis of the tracing showed an increase in the strength of the auricle which was quite marked while the ventricle was only very slightly affected. The heart rate was not lessened but increased twenty-five beats a minute. Into another dog of about the same size and prepared in exactly the same manner we injected 0.2 c.c. tincture of digitalis, and the tracings showed a very distinct increase in the strength of the auricle while the ventricle showed no change. The rate was slowed about ten beats to the minute.

A comparison of the results obtained in the two animals showed there is very little difference between the two forms of the drug when given in the corresponding doses determined by their relative effect on the frog. *The balance is in favor of the digitalin in that it did show a very slight effect on the ventricular systole,* while as regards the rate the tincture would have the preference. It is to be expected that the results would not correspond exactly, as in one case an approximately pure principle was injected while in the second a tincture was used.

This examination indicates that one reason at least why *digitalin fails in a large number of cases* is because it is not used in sufficiently large doses. For man the dose of digitalin to correspond with the usual 1 c.c. of the tincture would be somewhere about 1/5 grain instead of 1/100 grain. For the sake of safety we might cut this dose in half and say it should be 1/10 grain, which would still leave a great difference between the two amounts. The fact that digitalin should be given *in such large doses is by no means new.* Indeed, Merck gives the dose as from 1/10 to 1/2 grain. Among others who have recommended the larger doses may be mentioned Beates,[2] who prescribes 1/4 grain doses and in emergency 1/2 grain is given every two hours for a few doses. Administering it for months with occasional intermissions, he never saw harmful results to follow. Still more recently Arnold and Wood[3] call attention to the fact that 1/4 grain doses of digitalin are about equivalent to 1 c.c. of a tincture of digitalis (U. S. P., 1890, 15 per cent.). We conclude, therefore, that while *the digitalin tablets are fairly uniform in strength, they are made entirely too weak for ordinary use in practice.*

ERGOT.

We next took up the examination of a number of ergot preparations for the assay of which there exist several methods. The oldest, and that most generally used, is to ascertain the minimum amount of the drug which will cause distinct blackening of the cock's comb.[4] A second method, based on the recent work of Barger and Dale, consists in finding how much ergot it takes to transform the usual blood-pressure increase produced by adrenalin into a fall in pressure. This is the so-called "vasomotor reversal" method.

A third method, and *one recommended by Cushny and also by Kehrer, is to test the effect on the uterus itself.* The movements of the organ are recorded in the usual way by attaching levers to it and connecting them to a writing point arranged so as to register the contractions on the surface of a blackened drum. The animal is kept submerged in a warm saline bath during the course of experiment. Either cats or rabbits may be employed for the purpose, but we prefer the former.

By injecting varying doses of a standard preparation and of the unknown solution a very accurate estimate can be made as to their relative strengths by noting the size of the contractions produced by both solutions. In most of the animals 0.2 c.c. or 0.3 c.c. of a fluid extract will cause a distinct contraction. It was this uterine method which we adopted as being the most logical and satisfactory one, but no doubt each method will give good results in the hands of operators accustomed to their use.

---

[1] It may not be out of place to call attention to the fact, which is not generally known, that this method of assaying digitalis preparations by their action from the frog's heart was first carried out in the pharmacologic laboratory of the University of Michigan under the direction and at the suggestion of Prof. A. R. Cushny of London, who at that time was Professor of Materia Medica and Therapeutics in Michigan University.

[2] The Journal A. M. A., 1897, xxviii, p. 1209.

[3] Am. Jour. Med. Sci., 1900, cxx, p. 165.

[4] Houghton: National Dispensatory, 1905, p. 1728.

We assayed all our preparations against one of the fluid extracts which we have marked 1 in the table given below. In this table we have arranged the different specimens, giving the amounts which would be necessary to administer to produce the same effects as 1 c.c. of our standard preparation.

1	Standard } same manufacturer	1.00 c. c.	Physiol. assayed.
2		1.00 c. c.	Physiol. assayed.
3		1.00 c. c.	Not assayed.
4		1.25 c. c.	Physiol. assayed.
5		1.00 c. c.	?
6		1.00 c. c.	Not assayed.
7	same manufacturer	2.00 c. c.	Not assayed.
8		(see below)	Not assayed.
9		(see below)	Not assayed.
10	Hypodermic preparations } same manufacturer	2.50 c. c.	Physiol. assayed.
11		2.50 c. c.	Physiol. assayed.

Comparing these figures shows that five were practically alike; given in equal size doses they always produced corresponding results. One (No. 4) was about four-fifths of the strength of the others. Four (Nos. 6, 7, 8 and 9) are especially important, being made by one firm which makes no physiologic assay of their products. Of this group No. 6 gave good results; No. 7 required 0.5 c.c. to give a contraction equally strong to that produced by 0.25 of our standard. No. 8 we found to be practically inactive when given in doses up as high as 1 c.c. and 2 c.c., although our control was giving good results with 0.3 and 0.4 c.c. No. 9 when examined in February, 1908, gave contractions about equally strong as No. 1, but examined again in May proved inactive in 0.5 c.c. and 1 c.c. doses. Apparently it had deteriorated in the meantime.

Nos. 10 and 11, prepared for hypodermic use, were diluted with salt solution to fluid extract strength and then injected. They proved very weak, requiring 1 c.c. to give as good contractions as 0.4 c.c. of our control.

Referring again to Nos. 6, 7 and 8, it is interesting to note that they were made by the same firm that made the four specimens of tincture of digitalis one of us reported on last spring. These tinctures varied from one another as regards strength in the ratio of 1 to 4. At that time the firm had announced their intention to start physiologic assay work, but since then they have apparently experienced a change of mind, as they "do not think it right to control the effect of their medicines on man by experiments on the lower animals." After a survey of the varying strengths of their preparations comment is entirely superfluous.

In conclusion we think that no stronger argument could be brought forward as illustrating the necessity of the physiologic assay of these drugs than the results obtained with these eight preparations of ergot and digitalis.

ABSTRACT OF DISCUSSION.

DR. E. M. HOUGHTON, Detroit: I do not understand Dr. Edmunds' method of figuring the strength of the nitroglycerin. In my work on the assay of adrenalin and various other drugs by physiologic methods, I have found that it was always desirable to compare the unknown with the known under the same conditions. Was this done with the nitroglycerin preparations? In the routine assay of adrenalin and in conducting a few blood pressure experiments with nitroglycerin, I have found it desirable to determine the quantity of unknown which would produce the same rise or fall in blood pressure as a definite amount of the known, and from such data figure directly the percentage strength of the unknown required to produce the same physiologic activity as a definite amount of the known.

The method of testing digitalin tablets employed by Dr. Edmunds is the same that I have been using for the last ten or twelve years for the heart tonics, except that I have made the death of the frog the point for reading results, while Dr. Edmunds has taken the condition of the heart one hour after the injection of the drug as the time for making the reading. It has seemed to me that it was much better to adopt death as the final criterion, as is done in the standard test of antitoxins, etc., on guinea-pigs, than to attempt to read results from the physiologic conditions manifested by the animal. I believe that more accurate results may be obtained. We have found that with my method we can assay within 10 per cent. without great difficulty as a rule. Of course, there are difficulties; the frogs at certain seasons of the year vary more than under ordinary conditions. The Germanic digitalin as it appears on the market I have found, particularly during the last few years, to assay much more uniformly than it did prior to that time. I think that Dr. Edmunds is entirely correct relative to the dosage of digitalin.

I have recently had a number of experiments carried on to determine the value of the several methods that have been proposed for the assay of ergot. The reversal of blood pressure, by using adrenalin, has not worked satisfactorily on dogs. In fact, it is only in occasional dogs that you get such reversal. We have not tried rabbits or cats, but on dogs the results were quite unsatisfactory. Ergot is perhaps the most difficult of all the drugs that I have tried to assay by physiologic means. One must, by using the test of blackening of the cock's comb, be extremely careful of the fowls on which the experiments are done; otherwise errors will be made and no doubt different workers will get variable results.

PROFESSOR W. A. PUCKNER, Chicago: I believe that the profession does not realize the amount of work that certain manufacturing houses have done in this respect and that they have not received sufficient credit for their work. The manufacturing houses have been the pioneers in the standardization of drugs, and many firms have done much work which should receive more recognition from the members of the American Medical Association than it has. They have standardized many drugs and have received little return for it—not as much, I fear, as some manufacturers who have expended a like amount of money for printer's ink. Recently I examined a certain preparation and found one firm's product to contain only about 32 per cent. of what it was said to contain. I bought the second lot from the same firm and found it all right. I bought the third lot and it was all right. I then asked the manufacturer to explain, and I received the reply that apparently some mistake had been made in manufacturing the first lot. It is quite possible that these experiments will show that some of these drugs are deficient at times, though the house does not make a practice of supplying worthless drugs. But any one who sells medicine will have to take chances of having products shown up if they are not up to standard. When Professor Edmunds' paper is published I hope that it will contain the names of the manufacturers of drugs that were reliable and of those that were not. The paper will lose much of its value if the names of the manufacturers concerned are not inserted. In the laboratory of the American Medical Association some chemical examinations of drugs have been made, and the fact that not only the quality of products, but also their source, is published will make manufacturers more careful, more so than if only the statement that A's product is good and B's product is not good were published. On the whole, the result of Professor Edmunds' investigation shows that the drugs are fairly good. I am especially glad to see the nitroglycerin controversy ended. It seemed hardly possible that the statement going around a year or two ago, that all nitroglycerin tablets were inert, could be correct. I did not take much stock in it at the time.

Dr. Edmunds' work shows that nitroglycerin tablets are of fairly good quality.

How many fluidextracts are there that in ten years do not appreciably deteriorate? The fluidextract you buy is likely to be 10 years old unless you take precautions. There comes in the objection to the use of ready-made preparations of drugs. The preparations themselves will no doubt be found to deteriorate more than the drug itself. Shall manufacturers finally be obliged to put a date mark on each drug? I think C. E. Vanderkleed has shown that digitalis fluidextracts deteriorate 10 per cent. per year. That is a relatively small deterioration, but I am quite sure there are many preparations of digitalis that will very appreciably deteriorate with time.

Dr. M. Clayton Thrush, Philadelphia, Pa.: I think that this subject is one of most practical importance, as it teaches forcibly four important points: First, that manufacturing drug establishments, whether large wholesale houses or reputable retail pharmacists,should use—especially in all drugs that contain glucosidal or alkaloidal principles—only assayed drugs. In other words, only drugs which come up to the pharmacopeial requirements of a definite strength. The second point it teaches is always to use drugs from reliable houses. Unless Dr. Edmunds gives the names of the houses from which he obtained the drugs referred to, the paper will not be of near the value it would otherwise be to practitioners. It is important to know which houses do put out reputable preparations. Third, these investigations prove that some drug houses use drugs which are absolutely worthless. How do you explain that? Those of you who have been in the drug business—and I have been—know that you can get the same drug in qualities worth 20 cents, 30 cents or 40 cents a pound—any price you want—from wholesale druggists; and the strength varies often according to the cost. Therefore, if pharmacists buy drugs of lower cost the quality will be lower. I think that the majority of pharmacists put out reliable preparations. Unfortunately, financial considerations at times come into play. Take ergot, for example; from no drug is it more difficult to isolate the various active constituents which readily disintegrate; and after extraction they are prone to deterioration. If your order goes to some druggist who puts up only two prescriptions a day and buys enough stock for two years, you do not get the results you would if the ergot was fresh and up to date. This explains why some men have pessimistic views in regard to certain drugs. Fourth, the drug, even from the reputable houses and with their best efforts, will vary according to the season of the year the drug is collected, etc. I know that Dr. Beates frequently uses as high as one grain of digitalin at a dose, and, furthermore, that he is frequently called up by pharmacists wanting to know whether he is not using too large a dose. In using digitalin we do not, as a rule, give a large enough dose to get effects. We now know that the equivalent part is 1/5 grain, instead of 1/40 or 1/50, and you can readily see that from ½ grain up to a grain is necessary to produce the desired effect. The digitalin referred to is marketed as Merck's "Germanic pure."

Dr. A. S. von Mansfelde, Ashland, Neb.: We are told in The Journal of the American Medical Association that our Council on Pharmacy and Chemistry, for which I have the highest admiration, have examined a great number of drugs and that they fall into three categories: One category is absolute fraud, on which the Council speaks in no uncertain language; it is enjoyable to read. The other consists of tentatively accepted preparations; and then, unless I am mistaken, a great number which have been examined of which we know nothing. I am in the position of censor of the Nebraska State Medical Association of the advertisements that go into our state journal. I have endeavored very, very strenuously to inform myself and I am still very ignorant. The point has been exceedingly well taken that whenever a paper is read, on preparations that are below par, the author should have the courage of his convictions and say what is not good. Just look at it; we poor men in general practice are called in to a case of uterine hemorrhage, for example. We prescribe the drug we think will check it; we get a poor quality and let the woman pay the price of the experiment. Here is the matter in a nutshell: "Dear Doctor: I am informed you are very partial to Squibb's preparations." "You are correctly informed." "I want to assure you that our preparations are quite as reliable." "How can I prove this?" "Why, experiment with them," was the answer. I have neither time nor patience with that kind of performance. I learned the drug business more than forty years ago when it was necessary for me to make nearly every preparation in the Pharmacopeia myself, and in consequence here stands an old man who never prescribes a proprietary preparation. What is more, I will not prescribe even pills and tablets made elsewhere, and if I can not write a prescription for a pill or tablet and have my druggist put it up I am going to stop practicing medicine!

Professor W. A. Puckner, Chicago: The Council has so far chiefly taken up those preparations which have been voluntarily submitted by the manufacturers. I believe, however, that out of one thousand of the proprietary preparations now on the market which have not been submitted to the Council by their promoters nine hundred and ninety-nine could not be admitted, because they are in conflict with the rules of the Council. The Council repeatedly has discussed the desirability of publishing, besides a list of "accepted articles," also a list of all articles which have been rejected. It has always come to the conclusion that in the end more will be accomplished if only the most objectionable products are exposed. A great many products considered by the Council and rejected are being modified and corrected; when the reform is complete they will be accepted by the Council. This plan of action has, to a large extent, secured for the Council the cooperation of manufacturers, and I am certain has been to the best interest of the profession.

Dr. G. H. Hoxie, Kansas City, Mo.: Is there the same rate of deterioration in the sealed packages of ergot (e. g., those intended for hypodermic use) as in the samples mentioned by Dr. Edmunds? I endorse what has been said as to the importance of giving the names of the manufacturers of the samples tested. These discussions and reports are practically useless to the medical profession unless the investigators have the confidence necessary to tell whose and what products they are reporting on.

Dr. F. E. Stewart, Philadelphia, Pa.: The time has come when the scientific work done by manufacturing houses should be given due credit. Furthermore, it is important for those who are doing scientific work on the outside to consult with those who are doing scientific work in the laboratories of the manufacturing houses. I have known of several instances in which such cooperation has proved of mutual advantage. This especially applies to cooperation between the Council on Pharmacy and Chemistry and the manufacturers. If we could have more such cooperation between the Council and manufacturing houses it would be a good thing. As to the assaying of drugs—that is, the buying of assayed drugs and making them into preparations, claiming such preparations to be assayed—unless the finished product is assayed the claim is unwarranted. No manufacturer I know of would allow a fluidextract to go on the market until the finished preparation itself had been assayed to see whether the process of percolation had been complete. It is not safe to assume that the finished product conforms to the pharmacopeial standard because it is prepared from an assayed drug. The personal equation must be taken into account. One pharmacist is more skilful than another in extracting the drug by percolation, and the finished product will vary accordingly.

Dr. Torald Sollmann, Cleveland, Ohio: I may be misinformed, but I think that the name "digitalin" is applied to several very different preparations. Some of these have different toxicity, and in advocating large doses of digitalin which may be all right for one of these substances there is a good deal of danger if another should be dispensed. In such cases it seems necessary to specify the brand until we have a definite or accepted standard.

Dr. C. S. N. Hallberg, Chicago: The uniformity of medicines, of course, is the idea of the Pharmacopeia; not only to have purity and strength, but uniformity. Physicians must remember, however, that there are a great many drugs, particularly of glucosidal character, which vary considerably not only in their constituents according to the season and method of collection and so on, but also in that the constituents are not well defined. There are very few, comparatively speaking, glucosidal drugs that a chemist can analyze and state the composition of as he can of alkaloidal drugs or most other substances; and you will remember that to-day these very largely used drugs, digitalis and ergot, have no official standard simply because the Committee of Revision, six or seven years ago, were not able to fix standards for these drugs. There is no necessity for the physician to be particularly concerned over the lack of uniformity or variation in potency in the principles of these drugs if he uses the drug itself. For instance, in digitalis the only safe, satisfactory agent as a cardiac is the tincture, provided it is made from the finest quality of digitalis. Now, such can be had. Allen's English digitalis leaves can be had by any pharmacist if he will pay $1.25 a pound, instead of 20 cents a pound. But what difference does it make what the price is? It is one of the things that, when a physician wants, he wants badly; he must have it, and the pharmacist makes just as much on the drug of the second-year growth as he would on the cheap kind. If diuretic effects are desired the infusion is preferable. Dr. Beates, in this Section a few years ago, stated that he gave digitalinum Germanicum in doses of 1/16 grain. Now we are told he is giving ⅛. Next year perhaps he will be giving it in 2 or 5 grains, because it does not represent the properties of digitalis. And the same is true of ergot. There is no preparation to-day that takes the place of the well-made fluidextract of ergot such as Squibb's. There was no question of such fluidextract of ergot being efficacious, because every grain of ergot was picked out by hand. Many of you will remember the long tables around which women were seated picking over every grain. That fluidextract was allowed to stand three to six months before being bottled, and this gave it that peculiar ethereal odor which made it agreeable and serviceable. There are many constituents in plants beside the particular active principles. We have seen in this country active principles run the gamut from the resinoids in Cincinnati, where the pure principle (?) and whatever precipitated was collected and labeled with "in" and called an eclectic alkaloid or "concentration," while the real active principle often went down the sewer. We have the alkaloids from Ravenswood and other centers for exploiting the medical profession with active principles where they even discover active principles in magnesium sulphate or *Cactus grandiflora!* When the physician is in doubt about active principles let him find an honest, skilful pharmacist who will buy a quality of drugs which will insure their giving the desired results when made into first-class fluidextracts or tinctures. The less he believes that everything that comes from Germany is better than that produced in any other country the better for him.

Dr. C. W. Edmunds, Ann Arbor, Mich.: I tried the vasomotor reversal method on several cats, but did not find it very successful; in some even as large amounts as 30 c.c. of a fluidextract of ergot gave no distinct reversal, while a subsequent injection of 1 mg. ergotoxin (kindly sent me by Dr. Dale) gave the desired result. This phenomenon is shown much better on cats than dogs. I tried the cock's-comb method twice, but did not carry it further, as I got blackening of the comb from one specimen which proved inert when judged by the action on the uterus. As to the agreement of these preparations with the pharmacopeial standard, that is just where the trouble is—there is no such standard. Each manufacturer may assay his own preparation, but only to his own standard, which differs from other manufacturers' standards. So while we may be getting standardized preparations all the time they need not necessarily be alike unless they happen to come from one maker. What is needed is a national standard to which all manufacturers will agree. I can not say whether the sealed tubes of ergot deteriorate or not. Both specimens I examined were made by one maker and were alike but very weak. As to the original strength I can not say. I have assayed a tincture made from Allen's digitalis leaves and found that it was just about the same strength as the tinctures made from leaves obtained elsewhere.

I decided for certain manifest reasons that it perhaps was not best to publish the names of the makers of the various preparations which I examined. I believe, however, that such publicity will come in time, and when it does it will have a wholesome effect and will be but a matter of justice to those firms who are putting out reliable products.

OSTEOPATHIC VERSUS DRUG TREATMENT.[*]

M. CLAYTON THRUSH, Ph.M., M.D.

PHILADELPHIA.

> A concise exposition of the important principles of osteopathy and their relation to scientific medicine:
>
> "The most experienced surgeon knows nothing of anatomy in comparison with the educated osteopath."
>
> "The osteopath is a physician and surgeon in the best sense of the term, thoroughly conversant with the anatomy, physiology and pathology of the body."—*The A. B. C. of Osteopathy, 1907.*

During recent years a number of cults or sects have sprung into prominence, the cardinal features of the majority being an alleged cure of diseased states by the employment of other means or agents than drugs, which latter are decried and declared as poisonous and injurious.

Conspicuous among these is a system called osteopathy, and during the past few years, because of attempts to secure legal recognition, it has come into sufficient prominence to attract the notice of the members of the medical profession and the laity throughout the United States, as its disciples can be found in almost every village and hamlet in this country.

It has been one of the subjects for discussion at many of the local and state society meetings in the various states, especially since the osteopaths have been very active in legislative matters. There are now thirty-eight states that have laws recognizing and regulating the practice of osteopathy, and the medical profession, as a whole, has been disgracefully apathetic and deserves no credit for permitting this official recognition without most emphatic protest.

I sincerely believe that the majority of the members of our profession possess but a vague and indefinite knowledge as to what osteopathy really is, and the great majority of us have a very imperfect conception of its so-called principles and the precepts based thereon.

Realizing this fact, the object of this paper is to present a concise yet comprehensive view of this alleged science of osteopathy as defined in their standard text-books and periodicals, so that, by being familiar with its tenets and principles, we can intelligently work together as a body, first for the protection of the public and, therefore, indirectly for the higher interests of medical science and its art, on which afflicted humanity relies for relief, cure and the prevention of disease.

WHAT IS OSTEOPATHY?

Hulett, in his "Principles of Osteopathy," defines it as follows: "Osteopathy is a system of therapeutics which, recognizing that the maintenance and restoration of normal functions are alike dependent on a force inherent in protoplasm, and that function perverted beyond the limit of self-adjustment is dependent on a condition of structure perverted beyond these limits, attempts the re-establishment of normal function by manipulative measures designed to render to the organism such aid as will enable it to overcome or adapt itself to the disturbed structure." Thus the pathology of osteopathy repudiates science and explains typhoid fever, tuberculosis, scarlet fever, pneumonia, smallpox and other ills of humanity as due to misplaced tissues.[1]

---

[*] Read in the Section on Pharmacology and Therapeutics of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Osteopathic training is claimed so to augment the sense of touch that the fingers are enabled to locate the exact spot of the dislocation, and by osteopathic knowledge of anatomy manipulate, as no one else can, the tissues back to their proper relationship and thus cure the afflictions of humanity!

ORIGIN OF THE TERM OSTEOPATHY.

The term osteopathy is from the Greek words "osteo" (bone) and "pathos" (suffering) and literally signifies "bone suffering." But this does not refer to "bone disease" or "bone treatment," as we might suppose, but has reference to the chief basal fact of the body, viz., the order and mechanics of the body. It is on this fundamental idea of order and mechanical relation in the body that the alleged science is based.

ORIGIN OF THE SCIENCE.

The founder of the alleged science of osteopathy was Dr. A. T. Still, who for (a few) years was a practitioner of the erroneously called allopathic school. He announced publicly the principles of the new science at Kirkville, Mo., in 1874.

OSTEOPATHIC EDUCATION.

The osteopathic schools, according to Dr. (never received M.D.) O. J. Snyder, president of the Pennsylvania Osteopathic Association, are well versed in general medicine, and they claim to have had originally four terms of five months each, but recently this has been changed to three terms of nine months each. The reason for this change has not been given. The total number of hours devoted to the complete course is about the same as in the average regular medical school. They claim to teach everything the same as the regular schools, except materia medica, for which they substitute the principles of osteopathy. These statements are published in the March, 1907, issue of their leading journal entitled *Osteopathy*. As a matter of fact they teach the fundamentals erroneously, especially anatomy and physiology.

Now, if these statements are true that they teach the same subjects in as thorough a manner and devote the same number of hours to the subjects, then why do they object to the graduates of their schools passing the same examination as do the graduates of the other medical schools, and then be left to practice whatever branches of therapeutics they may elect? Because, like all sects, they wish to have sole control; their existence depends on self-control.

In other words, why not place all medical graduates on an equality, as they should be then required to possess the same preliminary education, a similar medical course for their degree and the same state board examination, differing only in substituting osteopathic manipulation for drugs under the subject of therapeutics in their college and state board work? Is not this a just and equitable arrangement? On therapeutics only do the allopathic, homeopathic and eclectic schools differ at present.

The only way to attain this end is one medical board made up of representatives from each system of medicine. This is what we desire the legislature of this and other commonwealths to grant for the protection of the educated physicians, no matter what the school, against the quacks, charlatans and incompetents who pose as physicians. This is all that we desire, and such an arrangement would be just as advantageous and protective to the properly trained osteopath as it would be to the members of the regular school.

In an address to the members of the legislature of Pennsylvania in 1907 by the Pennsylvania Osteopathic Association in support of the bill to regulate the practice of osteopathy, favorable consideration of their present bill is asked for the following alleged reasons:

> *First.*—Because osteopathy, as an accepted science in the practice of the healing art, has come to stay, as can be testified to by the thousands of its patients in Pennsylvania to-day.
>
> *Second.*—Because of the great success and popularity of osteopathy as a method of healing, the public are demanding protection from impostors and frauds, who are endeavoring to practice the art without the proper educational qualifications, to the detriment of the health of the credulous and uninquiring.
>
> *Third.*—Because all other forms of practicing the healing art, allopathy, homeopathy and eclecticism, are regulated and protected by the laws of Pennsylvania.
>
> *Fourth.*—Because the osteopathic profession desires only fair play and a square deal with other schools of medicine, and this bill provides that applicants to practice osteopathy shall take the same examinations as are required of those wishing to practice medicine, and that the state medical council shall issue licenses to practice osteopathy in the same manner as it issues licenses to practice allopathy, homeopathy or eclecticism.
>
> *Fifth.*—Because a consideration of the present bill will disclose that the osteopaths are ready and willing to adopt the same educational qualifications as required by the other schools, both preliminary and collegiate.

Now, if these are their true reasons for official recognition, as they pretend them to be, having presented them as such to our legislature, then why do they object to one medical board with proper representation? There can be but one explanation for an objection by the osteopaths: They do not intend to furnish the same qualification for licensure. Otherwise they would not have presented their bill providing for a distinctive board composed of osteopaths. The reasons for this are obvious to any one.

THEORY OF OSTEOPATHY.

According to the statements of the leading osteopathic authorities the osteopathic treatment is purely mechanical and consists of manipulations which seek to remove all obstruction to the vital forces of the body, and the theory on which it rests is that all diseases are due to some mechanical obstruction to the vital forces in the body, which may be removed mechanically without use of drugs. They claim that the method of treatment is based on a thorough knowledge of the normal and abnormal anatomy and physiology of the body.

THE CAUSE OF DISEASE.

Here the osteopath likewise differs from medical practitioners. The ideas held by osteopaths as to the etiology of the various diseases may be summed up as follows:

---

[1] Dr. Andrew Still in the January, 1908, issue of the *Ladies' Home Journal*, writing on the subject, "How I Came to Originate Osteopathy," makes the following statements: "I do not believe, and I say this after forty years of close observation and experiments, that there are such diseases as fever—typhoid, typhus or *lung*—rheumatism, sciatica, gout, colic, liver disease, croup, or any of the present so-called diseases. They do not exist as diseases. I hold that separate or combined they are only effects of cause, and that in each case the cause can be found and does exist in the limited or excited action of the nerves which control the fluids of a part of or of the entire body. The therapeutics of osteopathy are independent and original, and as extensive as the entire medical and surgical fields."

First.—Perverted Mechanics: That is mechanical derangement of the anatomic parts of the body. A very common cause of disease. Structure determines function. If the structural relations of the body tissues are all right, then the functions are normal, but if the structure is perverted in any way then the function is also perverted, and this is what we denominate as the cause of disease. This is the Magna Charta of osteopathic declaration, the golden rule of osteopathic procedure.

Second.—Bacteria: Bacteriology is alleged to be taught in every osteopathic school with the same exactness as in the best regular schools.

The osteopath has always held to the germ theory as the cause of certain diseases, but the osteopath does not use the same means to recover the health of a patient so infected, yet he recognizes that such conditions exist. The osteopath, emphasizing that disease is primarily of mechanical origin, holds, therefore, that germs are generally a secondary factor in the cause, and he believes that so long as the tissues of the body are healthy no germs can infect the body. There must be a suitable soil for the bacteria to live in or the bacteria will not cause infection. He further believes that if any part of the body is infected, and he can restore a good circulation of pure blood to the part so as to restore a healthy condition of the tissues, the invasion of bacteria stops *then and there. I should like to know what specific dislocations cause, respectively, the infections, as microbic diseases result from misadjustment of structure, according to osteopathy.*

The osteopath recognizes that disease may be due to toxic or poisonous compounds which may enter the system, but you will notice that the cause of the presence of toxic products is due to a perverted function, which is the result of a perversion of structure.

In case of the ingestion of a fatal dose of a poison, the osteopath would give the usual antidote and treat accordingly. They have a course in toxicology in their college course, claimed to be properly taught.

OSTEOPATHY AS A SYSTEM OF MEDICINE.

The osteopaths state that osteopathy is not a part of medicine and has nothing in common with it, other than the professed aim to cure disease. Its diagnosis and treatment are wholly unlike those of any other system of healing. The aim of medicine is to relieve symptoms, whereas osteopathy has for its object the removal of the cause. The regular physician treats symptoms, whereas the osteopath treats the lesion causing the symptoms.

OSTEOPATHY AS RELATED TO MASSAGE AND SWEDISH MOVEMENTS.

Osteopathy is claimed to be entirely distinctive from massage or Swedish movements, resembling them only in being an application of a mechanical principle. Massage and Swedish movements are only systemic exercises, whilst osteopathy is adjustment. Osteopathy is not exercise, and it is not given with the object of giving exercise to a patient, although in taking the treatment the patient receives a variable amount of exercise according to the lesion requiring adjustment.

OSTEOPATHY AS A SCIENCE.

The osteopath looks on the human body as a machine, and if the machine is in perfect order and harmony within itself then a state of health prevails. The bones form the foundation and framework of the body. The muscles and ligaments are strung on the bones, and the bones have more to do in determining the order and form of the body than any other tissue in the body. The nerves become irritated by physical, chemical, traumatic or other causes, and these irritated nerves cause the muscles and ligaments to contract, and this brings about more or less maladjustment in the body.

These maladjustments interfere with the function and are termed lesions, or the seat and underlying cause of disease. All diseases are due to lesions, and these lesions may occur in any portion of the human body. The osteopath claims that with a proper knowledge of the anatomy of the body he can detect these lesions, and the purpose of his treatment is to remove them and thus establish harmony and order in the body, which is the basis of health. The body being a vital machine, all it needs is to be able to perform its functions, and then it recuperates itself. Hence, by various manipulations, using the bones as levers, the purpose of the osteopath is to readjust a maladjusted body as structure determines function, and if we re-establish a normal structure then normal function will result. To cause this adjustment may require only a single movement, as in reducing certain dislocations as around the elbow or hip joints by rotating the arm or leg and pushing into position; or it may require several weeks' treatment, as where certain of the vertebræ are involved, and in giving the treatment the practitioner may have in view either or both of two objects. He works to right the spine and to affect it alone, or he works on the spine to affect some other part of the body pathologically connected with the part of the spine in question.

In the treatment of the spine, twenty-one different methods of manipulation are resorted to according to the lesions present, as described in Hazzard's Practice of Osteopathy. I will merely mention two of them to show the kind of methods that are used.

For relieving contractures and toning up flabby muscles the patient lies on the ventral aspect of the body in a comfortable position, the head is turned to one side, and the arms hang loosely down at the sides of the table. The patient relaxes all his muscles, and the osteopath stands at the side of the patient and uses the palm of the hand or the cushion of the fingers to thoroughly manipulate and relax all the spinal muscles. In treating the muscles on the side toward him he works from one end of the spinal column to the other in a direction at right angles to the general direction of the muscular fibers. He treats the muscles of the opposite side by spreading them away from the spinous processes.

In case of curvature or sagging of a portion of the spine, or lateral deviation of the vertebræ, the patient lies on his side, and the practitioner stands at the side of the table in front of the patient. With one hand he grasps the uppermost arm of the patient just above the elbow; the other hand he holds under the spinous processes or any portion of the spine under treatment. Now, using the arm as a lever, he pushes it downward and forward, at the same time springing the spine toward him.

In order to have a practical demonstration of this treatment I consulted one of our prominent osteopaths, a member of the faculty of the Philadelphia College of Osteopathy, and, as expected, I had a slight curvature of my spine, etc., which he manipulated, using a number of their classical manipulations. He informed me that each osteopath has certain manipulations characteristic to himself in addition to the classical ones, and he also told me that all that they do is to stimulate the circulation and make people "feel good." "That is why osteopathy is so popular."

THE OFFICE EQUIPMENT OF AN OSTEOPATH.

The office equipment usually consists of a reception room and one or more booths or "work rooms," in which there are a leather covered table and several chairs or couches. The patient, if a man, removes his top clothing down to his underclothes, except his trousers; and if a woman, after removing the outer garments in a similar way, she wears a loose gown during the treatment. "Their peculiarly sensitive sense of touch responds through two thicknesses of clothing, as they determine the lesions causing the disease with the *x*-ray tipped digital phalanges of their fingers which show the maladjustments of structure and dislocations." They certainly possess supernatural power of palpation and, strange to say, it is all acquired in three years!

As a rule, their offices are attractive and handsomely fitted up, even in the country towns.

CHARACTER OF CASES TREATED.

The majority of the patients are from among the middle and upper classes, as their treatments are rather expensive for poor people, although they have free dispensaries connected with their colleges. Their usual fee is $25.00 for twelve treatments, some charging more, some less. The time required for a treatment varies from ten minutes to an hour.

Osteopathy will never interfere to a great extent with medical practice, as the great majority of the patients are treated in the offices for conditions that allow them to be around, and if they are really sick with some acute disease, a regular practitioner is called, so that osteopathy is a sort of gymnastic specialty, as it were, and not invoked as yet for illness which regular practice confronts. Of course, some osteopaths attempt to treat serious cases, but they are in the minority.

Thus we have a clear conception of what osteopathy really is and stands for as stated by the leading authorities of their school.

Now let us consider the relations between osteopathy and the various branches of medicine, remembering that they treat all these affections solely by manipulation, as they are opposed to the use of drugs in the treatment of disease.

OSTEOPATHY AND GENERAL MEDICINE.

The osteopath represents himself as a competent clinician and treats all the various medical diseases, including the acute infectious diseases such as typhoid fever, tuberculosis, malaria, pneumonia, etc.

Diseases of Children.—The osteopath treats all the various diseases of childhood, including the contagious type, such as diphtheria, scarlet fever, etc., and he is opposed to the use of antitoxin in diphtheria and also to vaccination.

Ophthalmology.—The osteopath treats such diseases of the eye as granular eyelids, strabismus, pterygia, partial and total blindness, eyestrain, etc., and he does it by manipulation alone, for according to their pathology these conditions are due to maladjustments. They treat practically all the usual eye diseases.

Diseases of the Ear.—In the treatment of diseases of the ear, the osteopath uses a head mirror and ear speculum. He treats various types of otitis, deafness, earache, etc. He uses and recommends antiseptic agents in solution, injected by means of an ear syringe, yet he claims to be opposed to drugs!

Diseases of the Nose and Throat.—They treat the various affections of these parts, including such diseases as laryngitis, tonsillitis, parotitis, pharyngitis, stricture of the esophagus, etc.

Neurology.—They treat the various nervous affections, such as chorea, epilepsy, locomotor ataxia, paralysis agitans, etc.

Diseases of Women.—Diseases of women are a most important part of osteopathic practice, and they make vaginal examinations for the purpose of diagnosis, and in giving treatment they not only treat the patient along the lumbar portion of the spine, but also treat through the vagina, especially in such conditions as uterine displacements and prolapsus. They treat various menstrual disorders, ovarian and tubal inflammations, leucorrhea, uterine tumors, carcinoma, etc. Some of their treatments for gynecologic conditions are of especial interest, and they have special text-books on osteopathic gynecology. The following is a good example: In Hazzard's Practice, page 418, for the treatment of uterine hemorrhage the following procedure is recommended: "Often a quick, rather hard jerk at the hairy covering of the mons veneris is sufficient to contract the vessels and stanch the flow. Stimulation of the clitoris is also an important means."

Obstetrics.—Osteopaths treat and deliver pregnant women and recommend special procedures to aid in the delivery of the child. A few of their special manipulations are of interest, as recommended on page 418 of Hazzard's Practice. To deliver the placenta "a quick pull at the mons veneris will aid in expelling it." "Desensitize the clitoris to stop after pains."

Genitourinary Diseases.—They treat orchitis, varicocele, enlarged prostates, impotency and even gonorrhea and syphilis. Gonorrhea is usually readily cured without the usual sequels (page 422, Hazzard's Practice), and it is done by manipulations which "frighten the gonococcus."

Orthopedic Surgery.—Osteopaths make a specialty of reducing deformities and dislocations; hence they treat all the affections classified under this heading, such as spinal curvatures, Pott's disease, etc.

Diseases of the Skin.—They treat the common skin diseases, especially those of systemic character, including syphilis, etc.

Surgery.—Osteopaths recognize surgery as a branch of medicine at times necessary, but some of the treatments that they recommend before resorting to surgical means are particularly interesting. One will suffice to illustrate some of the barbarous and dangerous procedures that are advised in their text-books and carried out in actual practice among civilized people throughout the United States.

In Hazzard's Practice, page 174, we read under treatment of intestinal obstruction: "Some writers recommend thorough shaking of the patient. The patient is held by four men by the arms and legs, first with the abdomen upward, then downward, while the shaking is done. There should be much persistence in the treatment." This treatment would certainly relieve the obstruction, especially if the intestines are soft and gangrenous, but the undertaker's services would be required a little later as an adjuvant to the treatment.

LIMITATIONS OF OSTEOPATHY.

Hence one can readily see from the above classifications that osteopathy has no limitations, as they claim to cure every disease that ever has existed or ever will exist, as can readily be proved by an examination of Hazzard's work on the practice of osteopathy. They even treat pneumonia, typhoid fever, tuberculosis, acute nephritis, uremia, smallpox, parasitic diseases, such as those caused by various intestinal worms, and even tumors melt away as snow under the midday sun, according to their authorities.

DO OSTEOPATHS USE DRUGS?

It is frequently stated that osteopaths condemn the use of drugs and are opposed to them. A few examples will prove the falsity of such statements. As stated before, in the case of acute poisoning, the usual chemical antidotes are ordered, and they are taught these in their medical course. In Hazzard's Practice, page 390, we read under treatment of variola: "The ordinary methods of preventing pitting by keeping the face washed with a carbolic or mercuric chlorid solution and covered with clean cloths saturated with warm water should be used."

Again, on page 394, under worms: "For tape-worm the patient should then drink quantities of pumpkin-seed infusion or eat a gruel made of mashed pumpkin-seed."

On page 353, under myxedema, we read: "It seems that in these cases thyroid feeding, a treatment regarded as specific, would be necessary."

On page 227, under the subject of chronic cystitis, we find: "In this form and in septic cystitis, washing out the bladder is a valuable aid to the treatment. For the chronic cases, sterile normal salt solution (40 to 60 grains to a pint) or weak solution of mercuric chlorid (1:50,000 or 1:100,000) are recommended. For septic cases, a saturated solution of boric acid may be used. Their explanation of microbic infection is here overlooked.

On page 162, under cholera infantum, we find: "Hot injections are valuable measures, aiding in the removal of the irritant material from the bowel. A mustard plaster over the abdomen relieves pain." These statements are taken from one of their leading books on the practice of osteopathy. But how in the world any one can stop the growth of diphtheria bacillus in a child's throat by raising the clavicle and pressing the first rib downward and forward, working at its central articulation to correct the position of its head, is beyond my comprehension. Or in the case of hemorrhage complicating typhoid fever, inhibition of peristalsis should be done by work from the ninth dorsal vertebra down along the lumbar region. How this checks hemorrhage I should be pleased to hear some one explain. In my judgment, it would increase it, and if manipulation is very vigorous the danger of perforation would be greatly intensified, yet this is the treatment recommended.

Also, where a child is suffering from infection with the oxyuris vermicularis around his rectum, how raising the lower ribs causes their expulsion requires a little Christian Science faith to comprehend, does it not? Their vasomotor arc explanation is disproved by the facts of physiologic science!

Several of the patients who have been treated recently at the Philadelphia College of Osteopathy have been advised to use certain medicaments at home when manipulations did not relieve them, as they have told me personally, yet the osteopaths state that drugs are poisonous and injurious and they are opposed to them. I have seen prescriptions in drug stores written by osteopaths!

OSTEOPATHIC STATE BOARDS.

Now, what are the objections to the osteopaths receiving official recognition in the various states and being licensed as the result of examinations before state examining boards composed of osteopaths?

1. They are not required to possess the same preliminary educational requirements as members of other medical schools, some of their graduates not even possessing a grammar school education.

2. The course is completed in three years, while regular practitioners are required to take four years.

3. They represent themselves as physicians when using the title Doctor, and they treat every disease that is known, whether they can do good or not, manipulation often imperiling the life of a patient when suffering from certain affections, like tubercular arthritis or intestinal obstruction, etc.

4. They treat any one who applies to them whether they are under the care of another physician or not; hence have no code of ethics, except to use a name and collect the fee.

5. They treat patients in conjunction with practitioners of other schools, illustrating that the commercial weakness of birds of a feather affects the medical profession as it characterizes man everywhere.

6. A number of them secretly treat patients who are under the care of a regular physician.

7. If a patient's condition becomes serious they promptly drop the case and have the family send for a physician. They do this only because they can not fill out death certificates. License them and they can. That is what they desire.

8. They occasionally write prescriptions for drugs or give verbal orders for their use, notwithstanding their claim that they are opposed to the use of drugs as remedial agents.

9. They have not the slightest knowledge of the proper phraseology in the construction or writing of a prescription.

10. If they should become licensed, they will not confine themselves to manipulation, but will attempt to practice regular medicine as well, thus antagonizing their own statements by using drugs and baths, yet they claim to oppose them.

11. They presume to pose as expert witnesses in litigation.

12. They are opposed to vaccination, the use of serums, such as diphtheria antitoxin, and other agents, such as electricity, *x*-ray and hydrotherapy.

Now, what is the cure for the present existing conditions in the medical profession throughout the United States?

1. A one-board bill with proper representation, the same educational requirements and equal recognition to the graduates of all the various medical schools, the examination being the same in all subjects, except therapeutics, on which questions relative to the particular system of medicine studied should be asked, or the subject omitted entirely, allowing each one who receives the licensure to practice whatever system of medicine he deems best, i. e., protecting the public from the fearful consequences of incompetent practitioners by requiring

by law that everybody who offers his services and assumes the responsibilities of treating disease, deformity and injury, should qualify under one standard of knowledge, training and ability, and this opportunity free for all alike. There are forty-four states at present that have a one-board bill in operation.

2. This standard to be the same in each and every state in the Union, so that proper reciprocal relations would be established which would enable a physician receiving the licensure in one state to transfer and practice his profession in any other state should he so desire, and at any time.

3. Any physician addicted to drugs or alcohol, or convicted of criminal or malpractice, abortion or other practices contrary to the laws of his state, shall have his license permanently revoked, and said revocation to bar him from the practice of medicine in any other state.

4. A common standard of preliminary education should be exacted of every person desiring to enter a medical school anywhere in the United States, and every student should be required to pass this examination, no matter what his credentials are, not excepting a degree in arts or science; said examination to be about equal in standard to the present preliminary examination in law in Pennsylvania or New York or the equivalent of the present medical standard of the New York Board of Regents. This standard would debar a large number of students who do not possess the proper preliminary education and who are a disgrace to the medical profession.

5. Every applicant should be of sound mind and body and of good moral character.

ABSTRACT OF DISCUSSION.

Dr. Alexander S. von Mansfelde, Ashland, Neb.: There are very few members in this hall, I am afraid, who have not been guilty, when their patients have asked: "Have you any objection to my taking a few osteopathic treatments?" of answering: "Oh, I don't suppose it will hurt you. It is just massage." I hope that members of the American Medical Association will not hereafter commit the wrong of saying that osteopathic treatment is massage.

Dr. John Kercher, Chicago, Ill.: I wish to quote from a booklet by W. Livingston Harland, an osteopath, a definition of osteopathy assumed to be authoritative. When I get through I shall be glad if any one can enlighten me on the meaning, as I do not understand it yet, although I have read it several times: "Osteopathy may be formally defined as the science which consists of such exact, exhaustive and verifiable knowledge of the structure and functions of the human mechanism, anatomical, physiological and psychological, including the chemistry and psycho-physics of its known elements, as has made discoverable certain organic laws and remedial resources within the body itself, by which nature under the scientific treatment peculiar to osteopathic practice, apart from all ordinary methods of extraneous, artificial, or medical stimulation, and in harmonious accord with its own mechanical principles, molecular activities and metabolic processes, may recover from misplacements, disorganization, derangements, and consequent disease, and regain its normal equilibrium of form and function in health and strength." The volume is called "Osteopathy: The New Science." It stands as a sort of text-book for the osteopathic cult and the author, in his introductory, says: "This little volume, which we believe is the first that has ever been published in book form on the science of osteopathy," etc.

Dr. R. A. Lyman, Lincoln, Neb.: The osteopath surrounds some of the newer methods in therapeutics by a system of graft which is not understood by the layman. This fact medical men should remember. To the layman's mind osteopathy and massage are one and the same. A short time ago a prominent member of the faculty of the University of Nebraska asked me what I thought of osteopathy. He had been treated by an osteopath, had been benefited, and now praised the "doctor" highly. I gave him the substance of the "system." He had supposed that osteopathy and massage were identical. When I took the trouble to explain that massage is but one of the methods of treatment that has been used for years by the regular profession he regarded osteopathy in an entirely different light. Psychotherapeutics and Eddyism are identical in the mind of the average layman. It is our duty to explain these fads to our patients. If this is properly done the average thinking man will get the proper perspective. Such a procedure on the part of medical men will do more towards eliminating these systems of graft than all the legislation which might be enacted.

Dr. M. Clayton Thrush, Philadelphia: I presented this paper primarily for three reasons: First, to show in a concise way what osteopathy really is and what constitutes its important principles. I have talked with many physicians on this subject and none could give me anything like a satisfactory explanation of the claims of osteopathy. Second, to show how dangerous it is. Every one in this room has been asked by a patient whether he should try osteopathy. Often these patients have a disease in which the methods used by osteopaths will do harm and may even cause death. Third, to plead for a one-board medical law. We have only ten states in this great union without such a law at present! Each man who practices healing, no matter what his cult, should be required to pass the same medical examination and with the same preliminary requirements, etc. We have only seven states which do not require every candidate to be at least a graduate of some reputable and chartered school of medicine; and with only seventeen states remaining which do not possess reciprocal relations, our work is almost but not quite finished. We want to get these seven states in line. When we do this we shall have this task complete. Do not forget the important facts which I have outlined in my paper and which prove that in recommending osteopathy you are recommending to your patients procedures that may mean death or at least harm to your patients.

MEDICAL VERSUS SURGICAL TREATMENT OF AMEBIC DYSENTERY.*

JOHN MILTON HOLT, Phil.B., M.D.
Passed Assistant-Surgeon United States Public Health and Marine-Hospital Service.
BROOKLYN, N. Y.

In a paper[1] read before this association in 1907, I advocated surgical treatment of all patients with amebic dysentery, in whom, after a fair trial of other forms of treatment, *Amœba coli* could be found in the stools.

In offering some definite time limit during which these various other methods of treatment could be carefully and impartially exhibited, before classing a case as chronic (and, in my opinion, surgical), I suggested a period of about a year.

In the discussion of the paper, Dr. A. J. MacKenzie, Portland, Ore., expressed the view that I had been too conservative in waiting a year before operating, and suggested that appendicostomy be performed if the disease proved resistant after six months.

The fact that this question is of such vital and practical importance is my justification for presenting another paper on the subject.

Another incident influencing the production of this paper has been the appearance, since last year, of several other articles dealing with different phases of amebic dysentery. The topic may not arouse the lively interest of all, but should a physician consulted in a case of amebic dysentery be unfortunate enough to acquire the disease, the question would then appeal to him very strongly.

---

* Read at the Annual Meeting of the Oregon State Medical Association, Portland, Ore., July 2, 1908.

[1] Amebic Dysentery, Chronic, a Surgical Disease, N. Y. Med. Jour., Nov. 16, 1907.

At one time I was a victim of this malady, and for five years I have made an exhaustive study of the subject in all its phases. I consider it an obligation, therefore, to record my observations, experiences and opinions, and leave for time and the majority experience of other workers in the same field to determine the course to be generally adopted for the greatest good to the greatest number. As it is now, too many of these patients are receiving too little serious attention, when their salvation could be worked out at the expense of but a modicum of mental energy.

All observers are agreed as to the marked tendency of amebic dysentery to resist all ordinary treatment and to become chronic; a fact which renders it all the more imperative for us to devote our best endeavors to the development of a rational, uncompromising plan of attack in dealing with the disease in its chronic form. We should not permit any case to run on indefinitely, because the patient is "doing fairly well," when it could be cleared up once and for all by simple surgical treatment.

In one of my cases reported last year, treatment by colonic irrigation was begun as soon as amebas were demonstrated, or about three weeks after the onset of symptoms. This treatment was continued daily for over a year, except on the day on which microscopic examination was made. Amebas disappeared from time to time, only to return. Undue exertion or ordinary physical fatigue always caused an exaggeration of the symptoms, and a life of semi-invalidism seemed a certainty. During part of that time irrigation was practiced twice a day (always once a day), care being taken by change of position to encourage the flow toward the transverse and ascending colon. Several hours were devoted each day to the careful, conscientious employment of the irrigation treatment, with the full hope that recovery would be the reward. Nothing was considered too much trouble. But while there were periods of improvement, symptomatic improvement—if we can speak of it as such—the parasites persisted, no matter what irrigating solution was employed. Hope began to wane. For a time ice-water irrigations were used, as recommended by J. P. Tuttle. The irrigator was filled with cracked ice and the solution allowed to stand in it for about twenty minutes before using, when as much as five quarts of it would be introduced at one time. As an indication of how cold the solution was, I would say that chipped ice still remained in the irrigator after the entire solution had been passed into the colon, and the hand, held against the abdomen over the transverse colon, could detect the ice-cold temperature of the skin of the abdominal wall, transmitted through all the structures and tissues between the palpating hand and the colon.

The sigmoidoscope was used, and it was seen that no lesions were present below the sigmoid. Operation was decided on in this case after one year, but owing to family reasons its employment was not possible until after two years.

Will anyone offer and prove a valid reason for continuing medical treatment indefinitely after an experience of this kind? It should be added, however, that this is not an isolated example, but, unfortunately, is the experience in a large percentage of cases.

Any man who has had both medical and surgical experience with this disease will firmly endorse my line of classification, with the principles of treatment as suggested for the two classes of cases, acute and chronic.

But it is not to those men of the profession to whom I would particularly address myself (except for confirmation and endorsement), but to those who have not given the subject particular study and to those who have treated all their patients medically.

In the persistent study and presentation of this subject my sole object has been to invite earnest dissent, as well as earnest support, to the end that the best and most practical procedure may be adopted, even though it be the exact antithesis of my conclusions. It is the eternal truth toward which I am striving, whether that truth in this instance confirms or disproves.

There are altogether too many patients with amebic dysentery who to-day are no better than they were six months after the onset of the disease. There are patients now in the United States in whom the disease has persisted for six, eight and even ten years. One might say that they could be treated surgically if they wished to be; but has appendicostomy been even offered to them? Has the profession been educated up to the point of offering, or better, of advising operation after a certain lapse of time? Evidently not, if we are to judge from the relative infrequency of the operation, and compare it with the large number of chronic cases.

According to the annual report of the director of health for the Philippine Islands, Victor G. Heiser, Passed Assistant-Surgeon, U. S. Public Health and Marine-Hospital Service, during the year ended June 30, 1907, there were 344 deaths due to amebic dysentery in the city of Manila, as against 288 for the preceding year.

For every death there are about twenty patients who live, which would make a total of nearly seven thousand cases for that year. When we consider that a large proportion of that number return to the United States and are scattered all over this country, it can readily be seen that amebic dysentery becomes a matter of importance to the general practitioner everywhere in this country, and the subject can not be dismissed because primarily a "tropical disease." Progressive practitioners indulging in postgraduate work should take opportunity to familiarize themselves with the *Amœba coli* under the microscope, and then interrogate the stools in "that case of intractable diarrhea."

When a patient presents himself for treatment with a history of "a running off at the bowels," as it is frequently characterized, automatic recourse to bismuth, opium, or similar drugs should not invariably follow. With rest, dieting and slight medication, an acute exacerbation of a chronic amebic dysentery will often yield, so far as the diarrhea is concerned, and one may be misled into thinking that a "slight attack of diarrhea" has been "cured." *There should be more frequent use of the microscope in these cases.* It should also be constantly borne in mind that a patient does not have to go beyond the United States to acquire this disease, as it has been shown by Tuttle that cases have occurred among those who have never been outside of New York.

Futcher[2] reports ninety-five cases of amebic dysentery contracted in Maryland and seventeen in eight other states, which gives an idea how widespread the infection was five years ago.

---

[2] THE JOURNAL A. M. A., Aug. 22, 1903.

Now, whether the disease be *considered chronic after* a year or after six months, I believe that when it becomes chronic it also becomes surgical.

On the other hand, while it remains acute, it also remains medical, with the single exception of those acute cases which grow steadily worse, even while under treatment. I do not advocate surgical treatment for both acute and chronic cases (with the one exception just stated), but assert that a case ceases to be a medical one as soon as it ceases to be an acute one.

While there may be debatable ground for the adherents of the medical treatment of appendicitis, there remains no tenable ground on which to justify continuation of medical treatment and exclusion of surgical relief in cases of amebic dysentery after they have ceased to be acute. In the latter case, one has everything to gain and nothing to lose. He has already lost all he can spare.

It will be seen, therefore, that all through the consideration of this subject the questions come up: When does a case cease to be acute? When does it become chronic? While that can only be stated approximately, that approximate borderland should be bounded by some definite limits, as: Not earlier than six months or later than one year; or, placing it within narrower margins: Not earlier than nine months or later than one year. Some set of principles should be established on which to govern our practice in these cases. The issue should be squarely met. If some such borderland is not established, procrastination only will result and patients permitted to suffer who could be relieved. It was for that reason that last year I suggested a working basis in these words: "Amebic dysentery, with lesions above the sigmoid, chronic for over one year, resistant to colonic irrigations, then become a surgical disease."

One year was suggested as meeting the demands of conservatism, as I have been actuated by a conservative inclination from the beginning. But if further experiences prove that a year is too long to wait, the proper level will be shown by the gauge of clinical experience.

In the *Military Surgeon* for January, 1908, there appears an article on "Ipecacuanha in Amebic Dysentery" by Surgeon Henry I. Raymond of the United States Army. While the enthusiasm of Raymond as to the permanent value of ipecac in amebic dysentery is shared by but few others, still, for the purpose of this paper, I invite attention to certain points of related interest.

At this point I wish to state that in my opinion there is no known drug which, taken by mouth, can be tolerated in sufficient strength in the upper alimentary passages to secure a destructive or toxic action on amebas in the colon. Quinin has proved to be destructive to the parasites when brought in direct contact with them; ipecac has not. And yet quinin irrigations have failed to cure in many cases, perhaps because the amebas have become encysted, and then imbedded beneath the submucosa, sufficiently remote and fortified to withstand the action of the quinin solution in the lumen of the gut, only to develop marked activity after a lapse of time, during which the patient has considered himself or has been considered as cured. This would account for the fancied disappearance of amebas from the stools in so many cases. Quinin acts on the *Plasmodium malariæ* in the blood, while *Amœbæ coli* are within the lumen of the intestine and are not approachable through the medium of the circulation.

For accurate scientific data of reliable clinical value I believe the stools should be carefully examined microscopically for many months and even years after supposed recoveries. It would be of value, too, if these examinations were made by an impartial observer rather than by the clinician himself.

I know of patients who considered themselves recovered, and were so pronounced by their physicians, who were free from all symptoms for three, four and five years, only to be stricken with severe acute attacks, in the meantime not having been beyond the borders of the United States.

In Case 4 in Raymond's article it will be seen that five months after reported recovery following ipecac treatment the report states that "a few sluggish amebas" were found. To be sure, this patient was in the Philippines at the time, but the time under observation after the treatment was discontinued was only ten months. During that time five microscopic examinations were reported, *amebas being present once.* The history of this case since November, 1906, would be of decided interest to workers in this field.

Raymond's Case 5 is reported as having been subjected to microscopic examination for only one month after treatment.

While it is not my purpose to belittle the ipecac or any other treatment, the ipecac treatment, by the majority of observers, has been found wanting in amebic dysentery, no matter what it may do in other forms of dysentery. With ipecac or without ipecac, with quinin or without quinin, with argyrol or without argyrol, if *Amœba coli* persist after a year amebic dysentery becomes a surgical disease.

In his well-known work on "Tropical Diseases" Manson says:

> I can offer no explanation of the action of any of these drugs (including ipecac) in dysentery. We use them quite empirically. Ipecacuanha and simaruba really seem to have some sort of specific action on the disease or its cause, but in what way it is impossible to indicate. Strange to say, ipecacuanha, which has been found so serviceable in India, Africa, the Brazils and elsewhere, has a very poor reputation as an antidysenteric in the United States (Osler); it has also signally failed in some English epidemics (Clouston); facts pointing to specific differences in the dysenteries of different countries.

If ipecac is of value even in a limited number of cases, give it a chance. Leave nothing undone in striving to *prevent the case becoming chronic;* then, having done all, treat it surgically.

To reiterate: Amebic dysentery, *in its initial acute manifestations*, is a medical disease. When it refuses to yield to medical treatment and becomes chronic, it then becomes a surgical disease, and no patient should be denied the permanent relief which surgical treatment holds out to him.

Anders[3] has said: "I believe that ipecacuanha is the best single remedy for the treatment of this disease, but it is not a specific, and not all patients can take massive doses."

Referring again to the *Military Surgeon* for January, 1908, Assistant Surgeon Robert M. Thornburgh of the United States Army, in an article on "The Treatment of Amebic Dysentery," says:

> From the writer's *observations* while in charge of the dysentery ward in the Division Hospital, Manila (part of 1905-6), the cases treated *solely by ipecac* or by ipecac combined with

---

[3] THE JOURNAL A. M. A., Aug. 22, 1903.

> quinin enemata, nearly always relapsed when the treatment was discontinued. . . . No internal treatment used by itself was successful in the hands of the writer in any case of these subacute or chronic cases. . . . Quinin sulphate . . . has been extensively employed with some undoubted cures and numerous relapses with fatal termination. . . . Ipecac can be given . . . to lessen the diarrhea. It lessens the number of stools, but *does not kill the ameba*. (Italics mine.)

Thornburgh thinks well of rectal injections of argyrol, although the cases he reports were only under observation nine months. But whatever the results of further study of the effects of argyrol, the *rationale* of my line of treatment would not be modified. The patients relieved by argyrol would not have to be considered from a surgical viewpoint. If future experience results in reducing the number of cases now becoming chronic, so much the better; then there will be fewer surgical cases. That would make a difference in numbers without any difference in the principle for which I contend.

Surgical treatment is not an experiment; it has an established place in the treatment of this disease, and I would gladly extend its benefits by heralding its virtues. In fact, it has been so well thought of that it has been employed in pathologic conditions of the colon other than those caused by the *Amœba coli,* and with marked success.

To give expression to the conclusions of other observers who have treated this disease both medically and surgically, I will quote briefly from an article by Surgeon Holton C. Curl[4] of the United States Navy, entitled "The Surgical Treatment of Dysentery." He says:

> The necessity for surgical interference was brought strongly to my attention by observing the number of cases admitted to hospital (Isthmian Canal Hospital, Colon) in fairly good condition, which grew steadily worse in spite of the best medical treatment by careful and experienced men. . . . what I call an "intermediate class" . . . where medical treatment does not check the disease, where the patient loses strength and finally dies, the pathologic condition apparently uninfluenced by medicine or ordinary irrigation. It is in this class, varying as it does between extremes, that I would advise operation, and in most of these cases, it is a *dernier resort*, offering the patient the only chance of recovery.
>
> In a condition where there is nothing to lose and everything to gain, the surgeon is tempted to operate in cases in which he feels that the chances are all against recovery. He realizes, however, that cases of this sort—apparently hopeless—will recover in a most surprising manner, and he undertakes the operation often to the detriment of his percentage of recoveries. I prophesy that the mortality percentage will be high until the medical man (as in appendicitis) learns to send his patients to the surgeon before it is too late. Even more than in appendicitis there is a tendency to procrastinate, to try some new remedy, until, when the patient finally reaches the surgeon, his chances are small.

Recently I received a letter from Dr. Jerome B. Thomas, of Brooklyn, N. Y., from which I shall quote. Thomas spent several years in the Philippines and was the physician in charge of the Government Sanitarium at Benguet. He writes as follows:

> I had an experience in treating a case of chronic amebic dysentery soon after my return from the Philippines that has led me to the same conclusion that you have reached. The patient was a personal friend of mine, and we tried diet, internal medication, sanitarium treatment, and all sorts of local treatment for almost a year, when we agreed on appendicostomy as a last resort. Within two or three days after the operation he had made decided improvement, and then his progress was steady and quite rapid. I feel sure that he would have died without the operation.

This is only another of the many examples of how the surgical treatment appeals to the progressive practitioner. It is so essentially practical that it is no wonder that it has been referred to by MacKenzie as "a marvel of ingenuity."

One of Rockey's patients, also a medical man, has said that he would not take $1,000 for the benefit that his appendix has been to him.

While all the literature on the subject is not available at this time, for the consideration of those who have not reached any conclusions in this matter I would mention the names of Weir, Tuttle, Rixford, Nydegger (U. S. P. H. & M.-H. S.), Arthur (U. S. A.), Curl (U. S. N.), MacKenzie, Rockey, Barbat, Willy Meyer, Beck, Elder (of Montreal), and many others who have employed surgical treatment.

In conclusion I would suggest that the *Amœba coli* may not be pathogenic to all men, as it is well known that all individuals equally exposed do not contract the disease. The so-called *Entamœba coli* may be the form of the parasite as observed in the stools of an individual not susceptible to amebic invasion. The so-called *Entamœba dysenteriæ* may be the same parasite developing greater activity coincident with morphologic changes in an individual having a susceptibility to the organism. Have *Entamœbæ dysenteriæ* ever been found in a case presenting no clinical symptoms And have *Entamœbæ coli* ever been found in a person sick with dysentery in whom no *Entamœbæ dysenteriæ* could be demonstrated? This may be a case of a distinction without a difference, a biologic distinction without a clinical difference.

THE PREVALENCE OF HYDROPHOBIA IN THE PHILIPPINE ISLANDS.*

F. W. DUDLEY, M.D.
Attending Surgeon, St. Paul's Hospital.
MANILA, P. I.

Notwithstanding the fact that the organ of the humane societies in the United States has denied the existence of hydrophobia as a distinct disease—and surprising as it may seem, many prominent (?) physicians are quoted in support of the assertion—I shall consider it as such.

While the object of this paper is to show the prevalence of hydrophobia in the Philippines and the necessity of making available modern prophylactic treatment to all needing it, a review of the literature as it stands to-day does not seem out of place.

DEFINITION.

Synonyms are rabies, lyssa, *la rage, Hundswuth, Wasserscheu, Tollwuth.*

Hydrophobia is an acute, specific, infectious malady of the central nervous system, as yet of undetermined origin, principally occurring in carnivora, and to some extent in herbivora, communicated from the lower animals to each other and to man by the bite of an infected animal and productive of symptoms resulting fatally.

---

[4] The Military Surgeon, October, 1907.

*Read at the Fourth Annual Meeting of the Philippine Islands Medical Association, Feb. 28, 1907. Owing to lack of space, this article is here presented in abbreviated form. A reprint, giving the article in full, may be had on application to the author, or will be sent to any address by The Journal A. M. A., on receipt of a 2-cent stamp.

The saliva was found by Grüner, in 1813, to be the vehicle of infection. In 1823 Magendie proved that the saliva of hydrophobic patients was capable of conveying the disease to dogs, and this was confirmed by Eckel and Renault. The evidence of the communication of the disease from man to man is incomplete, but it should be held that it may be so conveyed.

The specific cause of the disease has not been isolated. It is customary to restrict the term "hydrophobia" to the disease in man, and rabies to that in animals.

The term "hydrophobia" is, however, not strictly accurate, as there is not necessarily any fear of water during the height of the disease, but only great difficulty in swallowing liquids; the attempts to swallow bring about attacks of convulsions, and not uncommonly the mere sight of water or other substance produces similar attacks.

HISTORY.

Democritus gives a clear description of rabies occurring in animals 500 B. C., and Aristotle, in 322 B. C. states that the human species is exempt from infection by animals. The first description of its occurrence in man did not appear until 200 B. C. Since this time many ancient and modern writers have contributed to the literature on this subject. The best description in modern times appeared in 1850, by Trousseau.

The first record of the appearance of the disease in England is in 1026. In 1768 rabies was alarmingly frequent in Boston and in other towns in North America. In 1779 it appeared in Philadelphia and in Maryland, and in 1785 it was prevalent all over the northern states and spread to the south. In 1860 rabies was again prevalent in America, especially to the west.

The cause of the disease was first clearly discussed by Pasteur in 1882, who devised a plan of rational treatment.

DISTRIBUTION.

Such authorities as Virchow have denied the existence of hydrophobia in Africa, Greenland, Denmark and parts of South America and Asia. He, and many others, asserted that it was peculiar to temperate zones. With a temperature of 25 degrees below zero, an epidemic broke out among animals in Greenland in 1860. In Russia hydrophobia is common and is due largely to the frequency of wolf-bites. It is relatively rare in North Germany, owing to the provision requiring all dogs to be muzzled. It is more common in France. Isolated sporadic cases occur in all countries of Europe, and, from time to time, epidemics varying in severity. It is usual for the malady to remain lurking in certain districts or countries. Thus foci of rabies are common in certain parts of Russia and of France, but rarer in central Europe. In Great Britain more or less extensive epidemics of rabies have occurred at different times. Since 1897, owing to the muzzling order, the disease has greatly diminished. During 1899 no human being died of hydrophobia in England or Wales a result which had not obtained during the previous fifty-one years. For the ten years ending with 1900, Tatham tells us that there was an annual average of 29 deaths from the disease. In the year 1900 11 cases were reported; this outbreak of rabies was confined to a district in the southwest of Wales. No death occurred in England from hydrophobia in 1903. For the period from 1899 to 1904 there were 2 deaths. Rabies is, however, more frequent in Ireland.

Salmon[1] shows that hydrophobia is of more frequent occurrence in the United States than is generally known. In the vital statistics of the census of 1890 the same author records 143 deaths from thirty states. The statement of Boulanger to the effect that no part of the world is free from the disease is probably correct.

That rabies is ever prevalent and widely scattered throughout the Philippine Archipelago is well known to residents of these islands, yet no cases could be found recorded in medical literature as occurring here. The scrawny, half-starved native dog offers little resistance to the inroads of any disease to which he is subject. He is found throughout the islands in great numbers, and his appearance would suggest a cross between a cur and some wild species of canidæ.

During a residence of about eight years in various parts of the islands I have become personally aware that rabies is a prevalent disease among native dogs, that people are frequently bitten by these animals, and that hydrophobia in man is not a rare result of such bites. I have a personal knowledge of 13 persons dying of the disease and 19 others who were bitten but did not develop the disease so far as could be learned. One of these patients applied to me for treatment at St. Paul's Hospital in March, 1906, four days after being bitten, suffering from a wound about the face. The patient developed hydrophobia sixty-seven days after being bitten, as near as could be learned, and died of the disease in five days after the first symptoms appeared. During the months of January and February, 1907, 6 persons were seen who were bitten by dogs said to have been mad.

During February, this year, the body of a dog which had bitten two persons, and was supposed to have been rabid, was brought to the government laboratory for examination. Dr. Strong states that no characteristic changes or Negri bodies were found in the central nervous system, and that rabbits inoculated had not developed any symptoms of rabies, February 27, 1907, nineteen days after inoculation.[2]

It is common in pueblos and barrios to see natives chasing mad dogs (*manga asong olol*, or *perros rabiosos*, as they are called in Tagalog and Spanish respectively) with long bamboo poles. The animals are killed in this way.

Dr. M. Murciano, Tarlac, Tarlac Province, Philippine Islands, in a letter to me, states it as his belief that rabies and hydrophobia are much more common in the islands than is generally known, and says: "The natives have great dread for rabid dogs and medical aid is seldom sought in the outlying districts, for they have come to know that hydrophobia, like the bite of the camamalú, a native snake, is certain death. For this reason but a very small portion of the cases become known to the health authorities." He continues: "Five of my own deer dogs and 14 dogs belonging to others have become affected with rabies, from my own personal knowledge, since 1900, and were killed by my direction."

Dr. Murciano has resided in the islands twenty-two years, was, under the Spanish Government, medico titular, Tarlac Province, is a close observer, a great deer-hunter and dog-fancier. Dr. Murciano's dogs are valuable, imported animals, and it is quite certain he would not have slain them unless he was convinced that they were affected with rabies.

---

[1] U. S. Dept. Agric., Year-Book, 1901.

[2] Since this paper was written, cases of rabies in dogs have been confirmed by pathologic examination.

According to native tradition, the islands were once free from this dread malady, and the infection was brought to these shores by seaweed, wreckage, etc.

With a view to collecting statistics on the prevalence of the disease, access was had to the records of the insular Board of Health and a circular letter was sent to every practicing physician in the Philippine Islands, including the army surgeons, early in February, 1907, enclosing a post-card for reply. These letters amounted to 521 in all, and 140 replies were received. From the records of the Board of Health,[3] for the years from Sept. 1, 1903, to June 30, 1906, in Manila, 2 deaths; 1904, 45 deaths in sixteen provinces, and for the year 1905, 44 deaths occurring in twenty-six provinces, making a total of 91 deaths from hydrophobia obtained from this source.

From the personal replies of physicians to circulars mailed (in addition to those reported to the Board of Health), 54 cases were gathered, which, with 13 deaths from my personal records, make a total of 158 deaths in human beings. Strange as it may seem, in reply to circulars sent out, but 17 persons bitten by dogs are reported in whom the disease did not develop. These, together with my 19 cases, make a total of 36 cases in which no symptoms of the disease were noted following the bite, so far as traced. This shows that the disease developed in only 1.16 per cent. of the total number of persons bitten. Of course, it is not known what percentage of the dogs inflicting these bites were actually rabid. The Board of Health only reports cases of deaths from the disease. As stated elsewhere, it is unusual for persons bitten to seek medical treatment, and few of those who develop the disease do so. My cases cover a period of from Oct. 1, 1902, to date. The cases reported by physicians in reply to the circulars mailed embrace the period from 1883 to Feb. 28, 1907, but only 7 cases were reported prior to October, 1902. Generally speaking, therefore, the cases reported in this paper may be considered as having occurred between Oct. 1, 1902, and Feb. 28, 1907.

Cases of rabies were reported as occurring in 253 dogs 3 cats, 1 carabao, 1 cow, 4 horses, 2 pigs, 3 rats and 1 monkey.

Of the thirty-nine provinces, the Island of Mindanao (Moro Province) and the district of Manila, in the Philippine Islands, twenty-three were shown to have been infected by the disease, as follows:

Ambos Camarines, Bataan, Bulacan, Cagayan, Cebu, Ilocos Sur, Masbate, Misamis, Pampanga, Pangasinan, Union, Samar, Nueva Ecija, Negros Occidental, Sorsogon, Tarlac, Tayabas, Albay, Capiz, Cavite, Iloilo, Manila, Rizal, Batangas and Bohol.

Thus, it will be seen, sixteen provinces escaped the disease, according to reports.

Since I mailed the circular letters requesting information regarding the prevalence of the disease I have received several telegrams from physicians addressed, inquiring if virus for protective inoculation was available in Manila, and requesting to be supplied, stating that they had patients under treatment who were bitten by rabid animals.

ETIOLOGY.

The idea that hydrophobia is less prevalent in winter than in summer is not correct. Suzor reports twice as many cases in March, April and May as in the summer months. Salmon, in a total of 14,000 cases, found June to be the highest month, and, though there were more cases reported from April to September, yet the difference is not sufficient to be of etiologic importance.

About two-fifths of all cases in man are in patients under fifteen years. More men and children than women are affected, owing to the mode of life and nature of the clothing worn protecting the latter.

The disease is never spontaneous, but is usually communicated through the bite of a rabid animal and the consequent inoculation with the virus that is present in the saliva. All domestic mammalia are susceptible to rabies, although, from the habits of the animals, the disease is most likely to occur in dogs and cats. Birds are more refractory than mammals, especially to bites, but they can contract the disease through inoculation. In the great majority of cases the disease is communicated to men by the bites of rabid dogs, occasionally of cats, and in rare instances wolves and foxes. Goats, hyenas and jackals are said to suffer at times. In 1888 a number of deer from the royal herd in Richmond Park, near London, suffered from the disease and were studied at the Brown Institution. Rodents may suffer from the malady. Dr. M. Murciano, Philippine Islands, reports a case in a carabao (water buffalo) acquired from the bite of a rabid dog. Hydrophobia sometimes occurs in the cow, and is communicated by inoculation to the rabbit, horse and pig. In the western part of the United States the skunk (mephitis mephitica) is said to be very liable to the disease. A species of the skunk is found in the Philippines. One was recently killed in the grounds of a private residence in Manila. Persons sleeping in the open air, or tents which the animal can enter, are liable to be bitten. All are capable of communicating the malady to man. Although the cause of the disease has not been determined with certainty, it is known that the virus has a special affinity for the nervous system and is found in the saliva but not in the urine or blood.

Bertarelli has shown that the virus reaches the dog's salivary glands by way of the nerves and not through the blood vessels. Pasteur has found the poison abundantly present in the nerve centers, and has transferred the disease by taking bits of brain substance or medulla, derived from an infected animal, and inoculating them into healthy subjects.

The disease can be passed from animal to animal, from an animal to man, and from man to an animal, and it can be passed on from one to the other without rapidly losing its virulence. The transfer is usually made through some solution of continuity, commonly a bite, but it has occurred through a pimple, a very slight abrasion of the skin, by the animal licking the part, and it is said to have been transferred by the milk of a nursing mother.

Absorption of virus has taken place through healthy unabraded mucous membrane—nose and eye. It may be conveyed from the mother to the fetus.

Infection from bites on the back is slowest, owing, no doubt, to the clothing and the skin being thick and nerves few. With a thorough cleansing of the bite in this location and cauterization the person is more likely to escape the disease.

The virus of rabies is especially abundant in saliva and in the nervous system, both central and peripheral. There is some discrepancy among the testimony of observers as to whether the virus is present before the symptoms of the malady are well established. According to Nocard and Roux, the saliva of the dog may be virulent three days before the onset of the symptoms; according to Dowdeswell, the central nervous system is not virulent until the animal shows symptoms of the malady. All parts of the nervous system are virulent at the time of death, but in the earlier stages of the disease both bulb and cerebrospinal fluid are virulent. The blood, the lymph, the muscles, the liver and such secretions as the urine and seminal fluid are usually stated not to contain the virus. On the other hand, such glands as the salivary, the lachrymal, and the pancreas contain the virus, and it has also been found occasionally in the milk.

---

[3] Reports of the Bureau of Health for the Philippine Islands are not completed for 1906; completed reports from seven provinces show twelve deaths from hydrophobia. These deaths should be added to the statistics presented in the foregoing.

It is possible that the disease can be acquired by absorption through the gastrointestinal tract. Some animals, fed on carcases of animals dead of rabies, have died, while others have been unaffected. It is probable that an abrasion of the gastrointestinal tract is necessary for infection.

It has been asserted that the disease may arise from the bite of a healthy dog, but this is not the case. The mistake has arisen from the fact that a dog may communicate the disease while suffering from the initial manifestations of the illness, and before the characteristic symptoms have developed.

A case is on record in which a man contracted the disease by unloosening with his teeth a knot in a rope with which a mad dog had been tied. Dried saliva of a rabid animal retains its virulency for some days.

Cases are on record of hydrophobia having been acquired through a wound received during postmortem dissection of a rabid animal.

The virus is destroyed when exposed to a temperature of 50 C. for one hour and 60 C. for half an hour. Five per cent. solution carbolic acid, 1 to 1000 solution of bichlorid of mercury, acetic acid and permanganate of potash destroys the virus in the same length of time.

The most remarkable fact about the virus of rabies is the power that it possesses of increasing in the nervous system. In this respect it is unlike snake-bite, after which symptoms come on in excessive rapidity. It is found in the peripheral nerves and may be present in the suprarenal bodies. There is some evidence to show that the virus inoculated by bite reaches the central nervous system through the nerves, and for this reason lacerated wounds involving nerves are more likely to be followed by the disease. It is possible that the virus may be conveyed from the peripheral nerves to the central nervous system through the lymphatics.

Wounds about the face and head are especially dangerous; next in order in degree of mortality come bites on the hands, then injuries on the other parts of the body. The relative order is, no doubt, greatly dependent on the fact that the face, head and hands are usually naked, while other parts are clothed. It would also appear that the mortality depends, to some extent, on the richness in nerves of the part injured. Punctured wounds are said to be most dangerous, and lacerations are fatal in proportion to the extent of the surface afforded for the absorption of the virus.

The disease exhibits some resemblance to tetanus, in which it has been shown that the principal phenomena of the malady are produced by the toxic substances elaborated by the specific bacillus.

The bite of the wolf is said to be most dangerous, and the following in diminished severity in the order named: cat, dog and other animals.

Woodhead states that only 16 per cent. of those bitten by rabid animals become victims of the disease, while other authorities state that when no preventive measures are adopted, half or even two-thirds of those bitten escape. There is great difficulty in determining this question with accuracy, owing to the difficulty of obtaining evidence that the dog or other animal reported to be rabid was really so.

Horsley says that more than 15 per cent. of persons bitten by dogs become mad. The mortality of those bitten by wolves is not less than 40 per cent. According to Babes, the mortality of the latter is from 60 to 80 per cent. The reason for the wolf-bite being so dangerous is its severe lacerated nature. The bites from cats are more dangerous than those from dogs owing to the tendency of the cat to "fly" at and bite exposed surfaces, such as the face and hands.

The disease is usually communicated by a rabid animal wandering at large, often over great distances, and biting other animals, such as dogs, cats, horses and cattle.

FREQUENCY.

Rabies is not a common malady in animals, and hydrophobia is rare, comparatively speaking, in man. Sporadic cases are met with in animals in every large city during the year.

PATHOLOGY AND MORBID ANATOMY.

The pharynx, mouth, fauces and esophagus may be injected and the latter very edematous. The tongue is often swollen and of a dark red color and vesicular papules are noted on its under surface about the opening of the salivary glands. Pulmonary congestion is frequently seen, the mucous membrane showing points of hemorrhage. The stomach and intestines are congested and may present hemorrhagic erosions or even ulcers. The stomach and intestines usually contain no food, but, in animals, may contain numerous foreign bodies, such as rags, manure, pieces of wood, straw, stones, coals, hair, hay, etc. The spleen is congested and lungs engorged with blood and there are numerous petechial hemorrhages on the surfaces of the serous membranes.

Rabies can never be excluded by necropsy, as the animal may have been killed, and frequently is, on suspicion of having the disease, and at such an early stage that none of the postmortem phenomena of rabies are present.

In the dog the teeth are often broken and the tongue and buccal mucous membrane lacerated.

The most characteristic naked-eye pictures in postmortem examination are congestion of the fauces, larynx, trachea and stomach and fluidity of the blood. There are signs of congestion of the salivary glands. In some cases congestion of the central nervous system, more especially of the medulla, is visible to the naked eye.

The brain, medulla and spinal cord show small hemorrhages and large numbers of small round cells in the perivascular lymph spaces and around the motor ganglia cells, and progressive degeneration in the spinal nerve cells appear, consisting in chromatolysis and overgrowth of the nucleolus. There may be congestion of the peripheral nerves and sympathetic, and degeneration of the nerve-sheath and enlargement of the axis-cylinder.

Fitz has observed blood extravasation into the perivascular spaces of the brain. Soft thrombi occasionally fill the cerebral vessels, being most marked in the veins. The clots lack firmness and are of a dark color.

Changes in the nervous system have been carefully studied by Kolesnikoff, Balzer, Schaffer and Benedikt. The *tubercles rabiques* were later described by Babes and consist of pericellular accumulations of embryonal cells which finally take the place of the destroyed cell. The atrophy, inversion and destruction of the cerebrospinal, sympathetic, peripheral ganglia and plexiform ganglia of the pneumogastric nerve have later been described by Nelis and Van Gehuchten; they consider these changes diagnostic of rabies. These changes are brought about by new-formed cells derived from the capsule, which appear between the cell body and its endothelial capsule. These new-formed cells increase in number, invade the protoplasm of the nerve cell, and finally completely occupy the entire capsule.

Clifford Allbutt and Gowers have described an accumulation of leucocytes around the vessels and an infiltration of the adjacent tissue of the bulb with similar cells. Gowers says that the changes are most intense in the hypoglossal, glossopharyngeal and vagal nuclei.

McCarthy and Ravenel have studied twenty-eight cases of rabies occurring in dogs, rabbits and other animals, and found these changes in all but one case. The plexiform ganglia were affected in all the cases in which positive results as to the presence of rabies were obtained. In twenty-one cases the bulb was examined for the tubercle of Babes and positive results obtained in nineteen. Gordon concludes that the presence of mast cells corroborates his view that the spinal ganglions are the places of predilection for rabic virus.

In rare instances there may be a cloudy swelling of the kidneys.

BACTERIOLOGY.

The micro-organism of the disease has not yet been determined, though there is little doubt but that it is some form of organism capable of multiplying in the tissues and producing a toxic substance. It is possible that the bodies discovered by Negri constitute the virus. They are irregular in shape, usually varying from four to ten microns in size, appear in the central nervous system and are probably protozoa. Rivalta, Ferran, Foll, Spenelli and others have described a bacillus. Memo thinks that he has proved it to be the specific organism and says that he has been successful in producing the disease in rodents, dogs, and birds with the typical differences characteristic of each.

Bertarelli states that in more than a thousand tests the Negri bodies were never found in animals free from rabies: they were always found in infected animals with three exceptions. Their chosen site is the hippocampus major. These bodies are also found in the Purkinje cells in the cerebellum. These findings are confirmed by Poor. Bongiovanni, in researches on animals infected with street virus, constantly found Negri endocellular bodies, but these bodies were not found in rabbits infected with fixed virus. Materozzi, of the Catania Institute of Experimental Hygiene, and Bonne, of the Berlin Institute for Infectious Diseases, have also found these bodies constantly, but the latter does not believe them to be of a parasitic nature. They are found in the pyramidal cells of the cortex, cells of the pons, Gasserian ganglia, spinal ganglia and spinal cord; also in the protoplasm and occasionally in the processes of nerve cells. They have not been seen in the nucleus, but are frequently in immediate contact with it.

CLINICAL HISTORY.

The average period of incubation in the Philippine Islands would seem rather long, based on reports received. One authentic case has been reported with an incubation of ten days, and several other unsubstantiated cases of less time, but the latter have been excluded. The three longest authentic periods of incubation reported were eight, nine and ten months.

DIAGNOSIS.

Space will not permit a discussion of this subject. The following points should, however, be borne in mind:

Occasionally a neurotic or hysterical person, after being bitten by a dog or even after reading or hearing a description of hydrophobia, develops symptoms which resemble it. Burr reports an interesting case of the kind from Osler's clinic. The characteristic symptoms may be present, but they are comparatively mild and the affection does not develop. It should be remembered that pseudohydrophobia or lyssophobia, as the state is called, often develops as early as twenty-four or forty-eight hours after the exposure, and may not develop until a few months or even later; whereas true hydrophobia rarely develops in less than fourteen days. It usually runs a longer course than the true disease and recovery is the rule. He is apt to show a disposition to bite, which is very rare in true hydrophobia, and if he barks, growls or snaps, it is an imitation and not the true disease. Threats, inhalations of amyl nitrate and powerful electrical currents speedily cure the ailment.

Dr. A. T. Short, surgeon of the Coast and Geodetic Survey boat *Marinduque*, in replying to my circular from Ormoc, Leyte, Philippine Islands, reports a case of lyssophobia which occurred in Libmanan, Camarines Sur, P. I., in 1901, while Dr. Short was stationed there in the military service. In a house adjoining the military hospital there occurred a case of hydrophobia, the patient dying. In the same house lived a lad of eighteen years, who had been bitten by a dog two years previously. He developed the usual symptoms of pseudohydrophobia, owing, no doubt, to fright, and recovered.

Tetanus is differentiated from true hydrophobia by the presence of marked lockjaw in the former disease, and by the fact that in tetanus there is no dribbling of saliva and no expression of terror. The convulsions of tetanus are more tonic than in hydrophobia.

Landry's paralysis may require exclusion in the diagnosis of the paralytic form of hydrophobia.

DIAGNOSIS OF THE DISEASE IN DOGS.

The great disadvantage of the experimental method of diagnosis is the fact that, on an average, some three weeks are necessary in order to determine with certainty the presence or absence of rabies.

It is, therefore, of the utmost importance that the public should be taught not to kill rabid animals which have bitten human beings, as is now the custom in the Philippine Islands, and other places for that matter, but to isolate the animal and study his symptoms with the object of determining the treatment of the injured person. After the clinical diagnosis has been made the affected animal should be killed, and the clinical diagnosis confirmed by at once removing the brain and cord for examination for the presence of certain well-known changes in the nervous system, described in the foregoing under "Pathology and Morbid Anatomy," as well as for Negri bodies. The finding of the characteristic changes of the nervous system, Babes tubercles, etc., together with the Negri bodies, is considered sufficiently conclusive to warrant the institution of the Pasteur treatment at the earliest possible moment.

Mills has said that, however suggestive the symptoms following a dog-bite, the given case can not be assumed to be a case of hydrophobia until other possibilities are excluded.

PROGNOSIS.

No case of recovery from true hydrophobia, allowed to develop in man, is on record in which there was undisputed evidence that the diagnosis was correct. Reported cases of alleged recovery from this disease may have been of the hysterical form.

TREATMENT (HISTORICAL).

Thorp states that the powdered seeds of a species of strychnos, probably *Strychnos nux vomica,* have for several hundred years been used in China as a remedy for hydrophobia—probably on the principle of "similia similibus curantur." The dose, expressed in terms of the alkaloid, would be from 0.002 grams to 0.0036 grams.

There are many curious remedies used by the natives of the Philippine Islands, one of which is to burn the hair of the rabid animal inflicting the bite and apply the ashes to the wound. The brain is then incinerated and its ashes applied in like manner.

PROPHYLAXIS.

The treatment of hydrophobia is entirely in the line of preventive medicine, for once the disease is developed curative measures are not possible. By muzzling dogs, as is done in parts of Germany and England, the disease can be practically eradicated.

The local treatment of the bite is of great importance and should be instituted at once after its infliction.

1. A tourniquet should be applied if the bite be on an extremity.
2. The limb should be thoroughly scrubbed about the wound with green soap or other soap.
3. The wounded part should be excised as in tetanus, if it can be done without injuring important structures or causing great mutilation. If the wound can not be excised—only anatomic reasons, and not fears of scars, etc., should deter us from this measure—and is a punctured wound, it should be converted into an open wound by free incision.
4. The wound should be scrubbed again with green soap or other soap and then with bichlorid of mercury, 1 to 1000.
5. Pure carbolic acid and then fuming nitric acid should be applied. If these remedies are not at hand, other strong acid, and the actual cautery may be used, but nitric acid is preferable to the actual cautery.
6. The wound should be left open and packed lightly with gauze moistened in bichlorid of mercury 1 to 1000 and wet dressing of bichlorid of mercury 1 to 1000 applied for twelve hours, and then dry aseptic dressing, which usually does not require to be molested until the wound is healed, unless the nature of the wound has required extensive excision, when it must require time to heal, by granulation, and may require several dressings.

Cocain may be used hypodermically, if necessary, for excision or incision of the wound, and may be applied to the wound surface before cauterization.

The bite should never be sucked for fear that the one who sucks it may absorb the poison through an abrasion, and then, too, we must remember that the virus can be absorbed through the healthy mucous membranes.

If Bier's cups are at hand, suction may be thus artificially applied before and after the wound is incised or excised. If the bite be on an extremity, the Bier hyperemic treatment with the elastic bandage might also be tried.

It may be contended that the above treatment is unnecessarily severe and that after excision mild antiseptics alone are required, but when we consider the possibility of infection from the contact with the excised portion, that the disease is sure death, and that this treatment, if applied at once, offers a fairly good chance of recovery, it is believed that one is warranted in carrying it out, and that any sane patient will submit to it when the matter is properly put before him. It is unnecessary to keep a wound so treated open five or six weeks. It should be treated like any other open wound—packed and allowed to heal from the bottom. I have treated about twenty cases in this way and have had only one death, that in the case of a boy who applied for treatment several days after being bitten. How many of these patients were bitten by rabid animals is, of course, unknown.

Some may contend that the tourniquet is unnecessary, as the virus is transmitted by the nervous tissue alone. Blood inoculations in large amounts have caused the disease: therefore, in the present knowledge of the disease, it is well to apply the tourniquet.

Ballinger states, from statistics collected, that of all persons bitten, 47 per cent. suffer and die from hydrophobia. When wounds have not been treated, 83 per cent. succumb. When cauterized—some patients not very promptly—33 per cent. die.

PREVENTIVE INOCULATION.

Where there is any reason to believe a person has been bitten by a mad dog, the preventive inoculation treatment of Pasteur should be administered as soon as possible.

Warren described the "protective inoculation" as follows: "The patients are first inoculated with a cord fourteen days old, and the inoculation is repeated daily for nine days, each time with a cord one day fresher. In winter the oldest cords used are five days old, and in summer, cords that have been drying for four days are also employed."

The treatment is absolutely harmless, if properly employed, and is almost universally attested. Pottevin states that 17,395 cases were treated at the Pasteur Institute, Paris, between 1886 and 1895, and there were but 139 deaths. If the average mortality from inoculation is placed as low as 20, instead of 139 deaths, there would have been approximately 3,476 deaths.

Since the commencement of the Pasteur preventive treatment about 55,000 persons have been inoculated, with an average mortality of 0.77 per cent (Ravenel).

In the New York Pasteur Institute, 313 West Twenty-third street, under the directorship of Paul Gibier, of 1,367 cases treated during the decade ending Jan. 1, 1900, 19 patients died, a mortality of 0.66 per cent. The patients should be sent to the Pasteur Institute at once, since delay tends to diminish the protective power of the treatment. It is, of course, useless after the malady is well developed.

ANTIRABIC SERUM.

Under this heading in *Progressive Medicine* for December, 1905, is the following statement:

> In spite of the fact that hydrophobia has been known to be a preventable disease for many years, the belief in the necessity of having the prophylactic treatment carried out at an institute, often situated at a great distance from the patient's home, and not infrequently entailing great expense, has in many instances prevented the employment of this procedure. That this is not necessary is shown by two cases reported by M. Solis-Cohen, who carried out successfully the treatment in the patients' homes.
>
> The Pasteur Institute of the Department of Health in New York will arrange for a course of treatment for the individual case on receipt of the following data:
>
> 1. Name and age of the patient.
> 2. Location of bite, with its treatment.
> 3. Any information bearing on the diagnosis of the animal inflicting the bite.
>
> The institute also requires a brief report on the patient's condition two weeks after the end of treatment. If no symptoms have developed two weeks after the cessation of all treatment, the patient is considered out of danger. Angny, in discussing Cohen's paper, stated that he had also administered the Pasteur treatment in a patient's home.

Section 546 of the Laws of Georgia, 1906, empowers and directs the State Board of Health, as soon as practicable, to arrange for the preparation and manufacture in its laboratory in the capital, material necessary for the treatment and prevention of hydrophobia according to the method of Pasteur, and to keep constantly on hand the necessary material, sufficient in quantity, to meet the requirements that any exigency may demand, and to distribute the same free of cost to physicians and surgeons over the state for the treatment of such of their patients as have been bitten by animals suffering with rabies.

The injection of diluted virus prepared from the bulb into the veins is stated to confer immunity on the horse, but does not do so in the case of dogs and rabbits.

CONCLUSIONS.

1. It is thought that it has been conclusively proved that hydrophobia is sufficiently prevalent in the Philippine Islands to warrant the government in providing the necessary means for placing the Pasteur treatment within the reach of all by making the virus available in the larger centers in the islands.
2. The virus should be furnished, free of cost, to all physicians having persons under their care who have been bitten by rabid animals.
3. The government laboratories could prepare and distribute the virus.
4. When the Pasteur treatment has been made available popular instruction regarding the disease in animals, its transmission to man, the immediate treatment of the wound, the necessity of making a diagnosis, and what should be done to enable the health authorities to do so, should be undertaken by the insular board of health and through the public schools.
5. When it is known by the inhabitants that a safe, and, to a considerable extent, a sure cure for the disease is available, there will be a great increase in the number of cases reported.
6. Undoubtedly, in time to come, the government of the Philippine Islands will make available to all the modern prophylactic treatment of the disease through the government laboratories, and if the statistics here presented succeed to any extent in shortening that time I shall feel well paid for my trouble in collecting the cases presented in this paper.

In this excerpt space will not permit of a detailed description of the Negri bodies or of the technic usually employed for demonstrating them. For like reason remarks on the clinical history of the disease in man and animals, and on diagnosis, are omitted. Little that is new could be said under these headings.

I gratefully acknowledge cases reported by the following: A. Anguita, S. Suzuki, Diaz Perez, Ramon Lopez, Fernando Calderon, D. del Val, M. Garcia del Rey, S. Diaz Perez, Manuel Gomez, R. E. L. Newberne and Francisco Castaneda, Manila; Simeon Carlos, Roberto Toledo, C. Pineda, Andres L. Luciano, E. Santos, Pedro Joven and Antonio Alvendia, Pampanga Province; Tranquilino Gonzalez, Iloilo; J. Victoriano y Kosca, Matias Aznar and V. Solis, Cavite; Jose Mascunana, A. Ubalde, Tayabas; Octavio Amado, W. A. Wickline, Rizal; Trinidad Moreno, Batan; Ramon L. Lopez, Pio Valenzuela, Bulacan; M. Murciano, Tarlac; Lope de la Rama, Negros Occidental; A. S. Short, Coast and Geodetic Survey boat *Marinduque*.

A COMPARISON OF ALCOHOLIC AND WATERY EXTRACTS IN THE SERUM DIAGNOSIS OF SYPHILIS.*

JOHN W. MARCHILDON, B.S., M.D.
Instructor in Pathology in the Medical Department of St. Louis University.
ST. LOUIS.

A new phase in serum diagnosis was introduced by the determination that syphilitic antigen is soluble in alcohol and that such alcoholic extracts could be used in the same manner as physiologic salt solution extracts in the serum diagnosis of syphilis. This discovery was thought at first to be only of theoretical value[1] in throwing light on the nature of the chemical substances concerned in the binding of complement, since it showed by the solubility of these substances in alcohol that they were fat-like substances or lipoids.

Since the use of other substances like lecithin, sodium oleate, etc., as antigen might, through failures, reflect on the practical value of the reaction for the serum diagnosis of syphilis, Wassermann[2] insisted that the results of his reaction could be relied on only when extracts made with physiologic salt solution were used.

The variability of these extracts even when kept on ice, the possibility of their failure to bind complement with luetic sera from day to day, makes their use unsatisfactory and laborious.

The advantages to be derived from the use of alcoholic extracts are many. They are more easily made than watery extracts, since they do not need to be put in a shaking machine for so long a time. They do not require so much time to sediment and they clarify better. The upper clear portion alone is used so it is never necessary to centrifuge them. They may be kept at room temperature and in general retain their power for a longer time.

The following represents an attempt to learn whether the results obtained from the use of alcoholic extracts are equal to or possibly better than those of physiologic salt solution extracts. The question for discussion may be separated into three parts:

---

* From the Laboratory of the First Medical Clinic of the University of Berlin, Geheimrat His, Director.

[1] Landsteiner, Müller and Pötzl: Wien. klin. Wchnschr., 1907, No. 50.

[2] Internat. Cong. for Int. Med., Vienna, 1908; München. med. Wchnschr., 1908, No. 17, p. 928.

1. Will a serum react positively with a physiologic salt solution extract and negatively with an alcoholic extract, and vice versa?

2. Do non-syphilitic sera react positively?

3. If so, will the same parallel be established when alcoholic extracts are used?

The proper answering of these questions has an important bearing on the practical value of the reaction for the serum diagnosis of syphilis and necessitates, of course, the application of the test to as large a number of sera as possible.

Physiologic salt solution extracts of syphilitic liver and alcoholic extracts of syphilitic liver and normal human heart muscle were used throughout these reactions.

The serviceability of the extracts was tested first. An extract, in order to be serviceable, must in proper dosage react positively with a certain number of sera coming from genuine syphilitic patients with manifestations, and it must react negatively with a certain number of sera from non-syphilitic individuals. A further demand is that it must not of itself alone bind complement.

In the examination of each unknown serum for diagnosis controls are needed. The purpose of these controls is to compare the reaction of the unknown serum for diagnosis with that of known positive and negative sera and to show that the extracts do not alone bind complement. These controls are to be made in every reaction in order to show whether any change has taken place in the extracts from day to day, as sometimes occurs. Every serum was tested with the three kinds of extracts explained above.

1. In more than 150 serum examinations carried out in this manner the results have always been parallel. When a serum reacted positively with a physiologic salt solution extract it invariably reacted positively with the alcoholic extracts and vice versa. Not only were the reactions of alcoholic and watery extracts parallel when fresh sera were used, but also in the case of old sera which were formerly positive and later sometimes react negatively, as noted by Fleischmann and Michaelis as well as by others.[3] In a word, in no case was a serum positive with one serviceable extract and negative with another.

2. To answer the second question, as to whether any non-syphilitic serum would react positively, demands a consideration of the cases from which the sera were obtained.

For this work the blood was taken from two sources — from patients and from autopsies. L. Pick and A. Proskauer[4] have pointed out that blood serum obtained at autopsy is of equal value with normal blood in the serum diagnosis of syphilis. To this end I obtained blood from seventy-five autopsies from the pathologic department of the Krankenhaus Friedrichheim of Berlin.[5]

A consideration of the cases submitted for examination permits the following subdivisions:

I. CASES WITH A HISTORY OF SYPHILIS OR HAVING A STRONG SUSPICION OF SYPHILIS, AND GIVING A POSITIVE SERUM REACTION.

1. Cases of severe arteriosclerosis and heart insufficiency	4
2. Cases of tabes and paralysis	8
3. Cases of hydrocephalus and meningitis	3
4. Cases of aneurism	5
5. Cases of syphilis, with history of infection, symptoms present	9
6. Cases of syphilis, with history of infection, no symptoms	4
7. Cases of nose and throat diseases of a specific nature	8
8. Eye cases of specific character	2
9. Suspicious cases, gynecologic	3
10. Cases with obscure symptoms and findings belonging to internal medicine	6
Total	52

In each of these cases giving a positive serum reaction the clinician or the pathologist either found signs of actual syphilitic disease or was led to believe that the present trouble was due to syphilis.

II. CASES WITH NO HISTORY OF SYPHILIS AND NO SUSPICION OF LUETIC INFECTION, AND GIVING A NEGATIVE SERUM REACTION.

1. Cases of tuberculosis	21
2. Cases of sepsis and septic infections	17
3 Tumors	12
4. Cases of arteriosclerosis, nephritis and heart lesions	13
5. Cases of scarlet fever	3
6. Cases of delirium tremens	2
7. Cases of rachitis	2
8. Case of echinococcus cyst	1
9 Case of Hodgkins' disease	1
10. Case of pernicious anemia	1
11. Case of whooping cough	1
12 Cases of typhoid fever	2
13 Case of insanity	1
14. Cases of nose and throat diseases	14
15 Cases of eye diseases	6
16. Cases belonging to internal medicine	3
17. Healthy children	2
Total	104

It is important to note that sera obtained from patients with tuberculosis of the lungs, with carcinoma, and with sepsis, for the largest part, gave negative reactions. The few exceptions will be explained later; the findings agree largely with the findings of Elias, Neubauer, Porges and Salomon,[6] who report weak reactions in these diseases. In this connection it is of interest to refer to a specimen of blood serum obtained from a case of tuberculosis in the wards. A serum taken from a young woman who had had several operations for bone tuberculosis of an atypical character gave a positive result. Later the clinical diagnosis of syphilis confirmed this finding. All the other cases of tuberculosis, on the contrary, proved negative.

III. CASES WITH A POSITIVE HISTORY OF SYPHILIS AND GIVING A NEGATIVE SERUM REACTION.

1. Cases of syphilis having been treated	4

Fleischmann and Butler[7] and others have already emphasized the fact that syphilitic patients under treatment frequently react negatively.

IV. CASES WITH NO HISTORY OR SUSPICION OF SYPHILIS AND GIVING A POSITIVE SERUM REACTION.

1. Total number of cases examined with no history or suspicion of syphilis	107
2. Cases giving a positive reaction	4

The four cases giving a positive reaction are as follows:

1. Carcinoma of kidney	1
2. Appendicitis and sepsis	1
3. Typhoid fever	2

The first case was one of a very large carcinoma of the kidney with metastases, at autopsy. The patient was a woman of 40 years who had been a prostitute. No history or signs of syphilis, however, could be obtained.

There were thirteen cases of carcinoma examined, of which one gave a positive serum reaction.

[6] Wien. klin. Wchnschr., 1908, No. 18.

[7] Fleischmann, Paul, and Butler, William J.: Serum Diagnosis of Syphilis, The Journal A. M. A., Sept. 14, 1907, xlix, 931.

Specific infection could not be accounted for in the case of appendicitis which went to autopsy from perforation of the appendix and peritonitis. The patient was a young man, married, with two healthy children Eighteen cases of appendicitis and sepsis were examined in all, and only the one mentioned above gave a positive serum reaction.

The two cases of typhoid fever went to autopsy the same day and showed extensive lesions of typhoid and septic infection. Syphilitic infection could be practically excluded. Typhoid cases examined in the wards for control gave negative serum reactions.

The present work shows, as has already been noted by Weil and Braun,[8] that a positive Wassermann reaction may be given not only in syphilis but also in other conditions, such as typhoid fever, carcinoma and septic infections. In these cases in which a positive serum reaction was obtained, as these authors have described, and in my own cases, the pathologic processes, such as multiple metastases in carcinoma, and the last stages of sepsis in typhoid and appendicitis, were very far advanced.

Moreover, in these cases with no suspicion of syphilitic infection a positive reaction was given not only by the physiologic salt solution but also by the alcoholic extracts.

CONCLUSIONS.

1. Alcoholic extracts may be safely used in the reaction for the serum diagnosis of syphilis, because they in no way differ from watery extracts.
2. There are some non-syphilitic blood sera which give a positive Wassermann reaction. These sera, however, are so rarely met, and then only in such extensive pathologic processes, that they do not vitiate the clinical value of the reaction.

I extend my hearty thanks to Dr. Paul Fleischmann, clinical assistant in the First Medical Clinic of the University of Berlin, Geheimrat His, director, for the assistance and direction of this work.

3904 Laclede Avenue.

THE QUARANTINE OF SMALLPOX.*

H. M. BRACKEN, M.D.
Secretary and Executive Officer, Minnesota State Board of Health,
MINNEAPOLIS.

While all intelligent and unprejudiced thinkers who have had any experience in dealing with smallpox recognize the protective value of vaccination, the general tendency is to insist on quarantine as an additional safeguard against this disease. It is for us to consider:

1. What does quarantine accomplish?
2. Is it necessary?

Quarantine is an evidence of ignorance. As soon as the true cause of any disease is recognized attention is directed to its prevention in the first instance rather than to its suppression after the disease has appeared. For example, with tuberculosis we direct our attention to destroying the infectious agent rather than to quarantining the patient. Again, before the means of transmission of yellow fever was known the quarantine methods used in the attempt to control its spread were most rigid, but when the world came to know that only a mosquito could transfer yellow fever from an infected to a healthy person, quarantine was practically abandoned and attention directed to keeping mosquitoes away from the patients, to keeping them away from healthy individuals, and to the destruction of the mosquitoes capable of carrying the infection.

Consistency would suggest that we follow a similar course with all preventable diseases when we have learned how to control them. So far smallpox has been an exception to this rule. We have known for more than a hundred years how to prevent this disease, and yet quarantine of all those exposed to or associated with a smallpox patient, as well as the patient, is still the general custom. Public sentiment demands this, and too often the medical profession supports the public in this unjust demand.

To control any disease by means of quarantine we must restrain all infectious individuals during their entire period of infection. With smallpox this may be possible if the disease appears at the outset in virulent form and if municipalities are willing to bear the necessary expense of restraining all such individuals. But if the virulent form of the disease becomes epidemic, or if the disease prevails in mild type from the outset, practically nothing is accomplished through quarantine, for there will always be mild unrecognized or concealed cases at large during part if not the entire time of their illness. Under such circumstances, while the quarantine is a failure, it entails great expense on the public and on individuals. It also favors a continuance rather than a control of the disease, for it is conveying to the public a sense of safety that does not exist and thus encourages delay in vaccination in countries where compulsory vaccination is not enforced.

There is no objection to the isolation of smallpox patients, for we do not want the disreputable-looking creatures about. Those who are not protected by vaccination deserve no sympathy if they have reached mature years, and they, too, should be isolated or kept under rigid observation after an exposure to smallpox until it can be determined whether or not they are to develop the disease. To restrain or quarantine the immune, however, is an injustice which should not be tolerated.

Any one who will study without prejudice the course of smallpox must admit the protective value of vaccination. Why, then, is not every one protected? First, because people will not adopt such protective measures unless compelled by law so to do. Compulsory vaccination laws properly enforced will eradicate smallpox from any country.

Vaccination has been brought into disrepute by poor vaccine, by careless methods in vaccinating, and by the exaggerations and misstatements of the so-called antivaccinationists. It must be admitted that in some instances sore arms and even death follow vaccination, but when this happens the vaccinator is at fault rather than the vaccine, assuming that the vaccine is of good quality, as it should be in this country at the present time under government inspection. The production of all vaccine should be under some responsible governmental control. The punishment can not be too severe for placing on the market a vaccine that is not safe.

The vaccine may be ever so satisfactory, but if the vaccinator is careless or the vaccinated is not properly cared for, infection at the point of vaccination may follow. Such conditions are far more apt to occur in a country without compulsory vaccination laws than in one where such laws exist. Under compulsory vaccination laws the exact amount of vaccine needed can be determined in advance. If it is known that 40,000 births occur annually in a state, then that state should have an annual market for at least 40,000 vaccination points or tubes. The producer, knowing this fact, can plan for producing this amount under the most favorable conditions. Without compulsory vaccination laws the vaccine producer has *nothing to guide him in the* amount of vaccine to be produced. He must, therefore, try to keep a safe quantity on hand. If a smallpox scare arises there is at once a call for a large amount of vaccine. The producers' supplies will be exhausted and they will hasten to replenish, although the conditions for so doing *may be most unfavorable.*

---

[8] Wien. klin. Wchnschr., 1908, No. 26.

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

Careless methods of vaccinating should never be tolerated. They will exist, however, where there are no compulsory vaccination laws. A necessary accompaniment of compulsory vaccination is the public vaccinator, through whom the possibility of careless vaccination is reduced to a minimum.

Vaccination should be performed during infancy—by preference during the first six months of life. At this time the danger of infection at the point of vaccination is very slight indeed, for the child is living under ideal conditions. Still further, with compulsory vaccination laws the public vaccinator should choose his season for vaccinating. It is a well-recognized fact that vaccination should, if possible, be avoided during the hot summer months, both on account of the quality of the vaccine at that time and the condition of the individual to be vaccinated. In countries without compulsory vaccination laws vaccination is practiced only when the alarm signal is sounded. Children of school age are often vaccinated just before the opening of schools in the fall—the most undesirable season of the year from every point of view. The methods of vaccination in vogue in this country at the present time are such as to make us wonder that we do not have more infection following vaccination.

The antivaccinationists say that physicians are in favor of vaccination because of the fees they derive from it. This is absurd. A physician can not afford to vaccinate for the ordinary fee if he does it properly. He can make money on vaccinations only when he undertakes to vaccinate a great many people in a very short time—a kind of vaccination that should never be tolerated. Lady Mary Wortley Montague, in 1717, speaking of inoculation, said:

> I should not fail to write to some of our doctors [in England] very particularly about it if I knew any one of them that I thought had virtue enough to destroy such a considerable branch of their revenue for the good of mankind. But that distemper [smallpox] is too beneficial to them not to expose to all their resentment the hardy wight that should undertake to put an end to it.

The antivaccinationists do not look on protection against smallpox (vaccination) as did Lady Mary Wortley Montague on inoculation. Lady Mary said that the doctors would not inoculate for fear of reducing their business; the antivaccinationists say that doctors vaccinate to make money.

Vaccination should be free. The public vaccinators should be trained in their special work and should be careful and conscientious. Individuals should have the privilege, however, of choosing their own physicians as vaccinators if they wish, but such a private physician should vaccinate with as great care as he would do surgical work and should be paid a reasonable fee for his services.

Physicians have placed themselves under criticism by urging compulsory vaccination laws on legislators. The enemies of vaccination charge physicians with mercenary motives in giving such advice and the legislators too often listen to the ignorant ranters rather than to the scientifically trained physicians in such matters. Why *should physicians place* themselves in such an unenviable position? They should be satisfied with acting as educators, throwing the responsibility of legislation on the people themselves. As educators their influence should be against any attempt to control smallpox by means of quarantine.

In 1904, in the Conference of State and Provincial Boards of Health held in Washington, a committee was appointed to report on the advisability of the abandonment of isolation in the attempt to control smallpox. The argument of this committee was to be based on the following propositions:

> Whereas, In many parts of this country (at the present time) a mild variety of smallpox is prevailing, and first cases are quite generally unrecognized, thus making their complete isolation impossible and tending to spread the disease among the unvaccinated, and
>
> Whereas, The isolation of the many cases causes excessive expenditures in a fruitless attempt to restrict the spread of the disease, and
>
> Whereas, Isolation of smallpox patients is practiced chiefly for the protection of those indifferent or opposed to the only scientific means of preventing the spread of this disease, viz., vaccination; therefore
>
> *Resolved*, That a committee be appointed by this conference to consider this subject in all of its bearings, and report next year as to whether in states where the above described conditions exist the effort to control smallpox should not be confined chiefly to vaccination and revaccination, rather than to depend in part or in whole upon quarantine.

At the conference meeting of 1905 these propositions were thoroughly discussed, and while the majority of the state sanitary representatives were in sympathy with some radical action in favor of vaccination rather than quarantine as a means of controlling smallpox, no definite action was taken.

The Minnesota State Board of Health has taken a position favorable to vaccination and against any false teaching relative to the protective value of quarantine. It did this only after carefully considering the subject. It preceded the publication of its new regulations relating to smallpox by the publication of the following resolution:

> It having been established that smallpox will not occur in a well vaccinated community, and that all attempts to restrain this disease in a community not protected by vaccination by means of quarantine, will fail; that quarantine in a well-vaccinated community is unnecessary; that attempts to control the spread of smallpox by means of quarantine are unscientific, irrational, expensive and misleading; that in laying down strict rules for the quarantine of smallpox *sanitary* authorities are favoring unscientific and illogical methods for its control and are conveying false ideas as to the safety of the public, the Minnesota State Board of Health advises that after January 1, 1908, further attempts to control smallpox by means of quarantine shall be abandoned. *Meeting of the* board, Oct. 9, 1906.

The reason for postponing action on this recommendation until Jan. 1, 1908, was that time might be given those who wished so to do to provide for their *own and* others' protection through vaccination before adopting a change in regulations.

This action of the board greatly disturbed the antivaccinationists, who sent their agents through the state decrying the proposed action of the board months before the new regulations were made public. These regulations are as follows:

11. The local health officer having knowledge of, or having reason to suspect, the existence of smallpox, shall investigate, and at once place on the house where smallpox exists a sign setting forth the facts. This sign is to serve only as a warning to those who may wish to avoid the house, and not as an indication of quarantine. When the attending physician considers a smallpox patient as having recovered (no longer a source of danger) he shall report the fact in writing to the local health officer, who shall thereupon remove the warning card from the house. *The patient must not leave the house until after the removal of the warning card.*

12. The apartments occupied by a smallpox patient shall be deemed infected, and when vacated by death, removal or recovery of the patient shall, together with their contents, be thoroughly disinfected under the supervision of the local health officer.

13. Every physician shall immediately report to the local health officer, in writing, the name of every smallpox patient under his care, the state of his or her disease, and his or her place of residence. A report must be made for each case as it occurs in a family or household.

14. Every physician shall report in writing to the local health officer the death of any smallpox patient under his care within twelve hours thereafter.

15. The local health officer of any city, village or township must report within twenty-four hours to the secretary of the Minnesota State Board of Health all cases of smallpox occurring within his jurisdiction and the date of removal of the warning card.

When these resolutions were passed it was supposed that an old law was still in force which provided for the exclusion from school of unvaccinated children when smallpox prevailed in a community. It was thought that this would protect the young. It was found, however, that this law had been displaced by later legislation. The State Board of Health, at its regular meeting in April, 1908, passed the following regulations for the benefit of the unvaccinated:

17. Following an exposure to smallpox, every individual who can not show evidence of a recent successful vaccination or a recent attack of smallpox must be vaccinated within three days of the first exposure or placed under the same isolation restrictions as smallpox patients.

If smallpox prevails in a community, or if the disease appears in a school, all unvaccinated teachers and pupils must be excluded from school for a period of three weeks unless vaccinated within three days of first exposure. Failing to comply with this requirement, the school must be closed for a period of three weeks.

If smallpox appears in any class in any college in Minnesota, all unvaccinated teachers and students in the class must be excluded from recitations for a period of three weeks unless vaccinated within three days of first exposure. Failing to comply with this requirement, the classes attended by such teachers or students must be discontinued for a period of three weeks.

The board expected criticism from the laity for making such a radical change in its smallpox regulations, but it expected the support of the medical profession on apparently such a logical procedure. Strange to say, there were not only prominent physicians, but certain sanitarians, who criticised the board's action. The board still thinks it was right and trusts that other state boards will follow its example.

ABSTRACT OF DISCUSSION.

Dr. George W. Webster, Chicago: If a smallpox patient is isolated, but the nurse and family come in contact with the patient, and are allowed to come and go as they please, are they not as great a menace to the public as the patient, after he has partly convalesced?

Dr. G. B. Lake, Wolcottville, Ind.: I am a member from a country district where this smallpox matter has been agitated. We have had several smallpox epidemics, and this question has been largely talked over among us. In towns where the quarantine has been enforced very strictly it has been a decided burden, because when a family, no matter in how good circumstances it may be, is quarantined for smallpox, and the breadwinner compelled to refrain from his necessary labor, the general understanding is that that family must be supported, not simply with the necessities of life, but also with any luxuries to which its members may feel themselves entitled. A person of mature years who refuses to be vaccinated absolutely deserves no sympathy, and I believe that the cutting off of the quarantine laws with regard to smallpox will be the quickest and surest way of educating the people in the necessity of vaccination.

Dr. J. N. Hurty, Indianapolis: I endorse every word Dr. Bracken has said. There is not the slightest need of having smallpox. It is an indictment of the intelligence of a community for it to have the disease. There is only one prophylaxis for smallpox. Quarantine does not amount to a hill of beans. If a single patient comes into a community where smallpox has not been prevailing, isolation of that patient will probably stop the spread of the disease. If the disease gets started, as it did in Indiana, quarantine amounts to nothing. I am only sorry that we have a statute, which the board of health can not change, which requires that smallpox be quarantined. That is a useless expense. Down in our mining regions they love to be quarantined. If told that vaccination will protect them, the people will reply that they would rather have the disease than be vaccinated. The reason is that they will have a chance to lie around at home with support furnished for a while. They will run the risk of death, for they see that smallpox causes very few deaths. They care little for the inconvenience. It is in vain to tell them that we, being vaccinated, are not afraid of it, can not be attacked by it, can live with it—eat it, if we want to, or do as Dr. Brayton did, who inoculated himself with it over and over again, and carried the sore on his arm three months by inoculation to demonstrate that he could not have it. All this has no effect. What is the use of quarantine to control epidemic smallpox? Let those that want it have it. I regret that the Indiana statute which compels us to quarantine smallpox is repealable only by legislative act. On the Monon road to Indianapolis, in Carroll County, are about two hundred cases along Wild Cat Creek, some very severe. We just let them alone. They will never have it again. The health officer of Sullivan County took his thoroughly vaccinated child with him when he went to see cases, to demonstrate to the people of Sullivan County how to go free from smallpox. Of course, neither father nor son contracted the disease because they were successfully vaccinated. Even such demonstrations do little good. I endorse Dr. Bracken's contentions.

Dr. Heman Spalding, Chicago: It is immoral to advise that every one be allowed to get smallpox who wants it. One might as well let a man commit suicide because he wants to do so. Quarantine, of course, is secondary. Vaccination is an absolute preventive: if everybody can be induced to believe that and act on it there will be no more smallpox. In Oskaloosa, Iowa, I made such a statement before the city council. A member of the council said: "Let's go right out and get them all vaccinated." I said he might start out and try it; it would take one thousand to vaccinate another thousand. It is necessary to quarantine and isolate. Right out of Dr. Bracken's and Dr. Hurty's back doors smallpox patients are coming to Chicago all the time. It cost us $100 to take care of patients that Dr. Bracken has failed to quarantine in Minnesota, and the same is true of Dr. Hurty's state. We have four cases of smallpox in Chicago now, one from Montana, another from Tennessee, all four from outside of the city. Nearly all our cases are imported. We have this city so well vaccinated that smallpox patients can enter a car or hotel or any place here, and out of 500 people they meet, only one or two will be infected. Vaccination stands first, quarantine second. Quarantine can not be dropped under the present condition of affairs. I do not approve the method of Minnesota. It has made me turn gray this winter. We have had more trouble with that state than any other. Dakota is doing the same thing, and we have three or four cases from there. I am absolutely opposed to Dr. Bracken's paper as it stands.

Dr. C. F. Williams, Columbia S. C.: I think that Dr. Bracken is on the right line. I do not think, however, that exposed individuals should be allowed to run at large unless vaccinated. I agree with him that the shotgun quarantine does harm instead of good, for when such a measure is instituted cases are going to be concealed which otherwise would be reported. When the bread-earner is shut up it becomes necessary to feed his family, and in a very widespread epidemic it is not long until the city or county treasury is so depleted that a howl goes up from this quarter, resulting, as a rule, in antagonism against those trying to control the disease. In South Carolina we have a compulsory vaccination law. As soon as one develops the disease, patient and attendant are isolated, and all the occupants of the house and those exposed vaccinated. The occupants are then allowed to go in and out just as though nothing had happened. The public is warned by a sign, bearing the words, "Contagious Disease Here," which is placed by the entrance to the house. When the case is dismissed by the attending physician the house is thoroughly disinfected. By this means we have been able to control the disease, and in very few instances has a second case occurred.

Dr. H. M. Bracken, Minneapolis: In answer to Dr. Webster's question, we allow the vaccinated to go to and from placarded houses. That is exactly in line with the teaching of Dr. Chapin's paper this morning, and with the position taken by Dr. White yesterday. Dr. Gorgas says that the sick man is the great transmitter of disease. It is not the healthy individual who spreads smallpox; it is the sick, and we want to impress this fact, not only on the laity but also on members of the medical profession. I admit that there is a possibility of transmission by a second to a third party, but that possibility is so slight that we can ignore it, and not do any great harm in the community. We certainly can do more good by advising people that they must protect themselves by vaccination than by giving them the idea that we are going to protect them by quarantine. Dr. Spaulding says that smallpox is coming into this city from Minnesota. If that is so the Chicago Department of Health is not doing its duty. Dr. Evans was in Minnesota a short time ago, and took the position that if Minnesota wanted to have smallpox it ought to have the privilege, but that it was a question if outsiders should not quarantine against the state. I wrote to Dr. Evans, at that time, urging him to advise me of every case of smallpox found in Chicago from Minnesota. At that time he advised me of one case. We sent an inspector at once to the place in Minnesota from which this patient went and found smallpox patients not properly looked after. These patients were at once placed under proper control. We have not had notice of a single case of smallpox in Chicago from Minnesota since that time.

Pasteur Institutes in India.—The Pasteur institute for the treatment of hydrophobia is now in full swing at Kasauli, a small hill station in the Punjaub, on the road to Simla. Large numbers of Europeans come here from near and far for treatment, and soldiers are sent by the government free of charge from all parts of the empire. In some instances natives will travel immense distances in order to place themselves under treatment, although in most cases they can not be prevailed on to recognize the facts of the situation. Hydrophobia is terribly prevalent in India among dogs and jackals, but there is no particular reason why it should not be as amenable to preventive measures in India as it has proved to be in the British Isles.—*Medical Press and Circular.*

Clinical Notes

THE TREATMENT OF PERNICIOUS ANEMIA WITH CHOLESTERIN.

CHARLES E. SIMON, M.D.
BALTIMORE.

In a recent communication Reicher[1] reports three cases of pernicious anemia and one of secondary anemia referable to nephritis in which cholesterin was used for therapeutic purposes, the idea in mind being to counteract any hemolysins that might be active, in a manner analogous to the action of cholesterin on cobralecithid. Similar considerations led me to the same attempt over a year ago. But as I have had only six cases of pernicious anemia at my disposal during that time, I hardly thought my data sufficient to warrant their publication. Reicher's paper, however, makes it desirable to place on record the little that has been done.

All six were typical cases of cryptogenetic pernicious anemia, one of them being of the so-called aplastic type. Three patients were in an advanced state of the disease when coming under observation and only lived for a few weeks; in these no effect whatever was observed from the use of the cholesterin. A fourth patient was discharged unimproved after a three weeks' course of the treatment and died a few days later. In the fifth only 24 gm. had been administered when the treatment was suspended, and death occurred shortly thereafter.

An apparently beneficial effect was obtained in the remaining case, but as the patient at the time when the cholesterin treatment was begun was virtually in her first attack one naturally hesitates to ascribe the noted improvement to any one therapeutic factor. It is noteworthy, however, that the resumption of the cholesterin some months later, when a relapse had occurred, was again followed by marked improvement. This patient is still living and in good condition. When first seen the red cells numbered 1,744,000, while the hemoglobin was 46 per cent.; there was then marked anisocytosis with a distinct tendency to macrocytosis; there was poikilocytosis and extensive granular degeneration (so-called). Normoblasts with pyknotic and karyolytic nuclei were fairly numerous; there were some free nuclei and a few mitotic cells; megaloblasts were scant. After a three weeks' course of cholesterin the red cells had increased to 4,000,000 and the hemoglobin to 80 per cent. Anisocytosis was still noticeable but less marked than before; granular degeneration was slight and there were no nucleated red cells. Subsequently the anemia became more marked again, but, as I said before, the patient again improved and at the present time is well.

In Reicher's three cases of pernicious anemia one patient remained unimproved, while in the other two the effect of the cholesterin was decidedly beneficial. One of these patients was admitted in a wretched condition, with intense dyspnea, ascites, pleural effusion, edema and a red count of 750,000 with 18 per cent. of hemoglobin. After a week the count had risen to 1,750,000 and the hemoglobin to 30 per cent., while the threatening symptoms had all disappeared. The improvement was thus quite remarkable, but after a few weeks no further gain was obtained and still later a relapse occurred which ended fatally.

---

[1] Berl. klin. Wchnschr., 1908, Nos. 41 and 42.

As to the administration of cholesterin, Reicher made use of a 3 per cent. solution in olive oil, of which he administered 100 gms. a day—hence 3 gms. of the substance. In this manner he obtained a much better resorption than with aqueous suspensions. In future I shall follow the same plan; in the past I have made use of cholesterin in capsules. A serious drawback to the extended use of the material is its cost, viz., 50 cents a gram; this makes it doubly important to achieve as extensive a resorption as possible. Regarding its nontoxicity, Reicher's observations are quite in accord with my own; even with 4 and 5 gms. a day no deleterious results whatever were noted.

A theoretical discussion of the rationale of the use of cholesterin in anemias of the pernicious type does not seem necessary at present. The sole object of this communication is to place my results on record. So far as they go they seem to indicate that in advanced cases very little, if anything, is to be hoped for from the use of cholesterin, while in early cases improvement may follow.

THE INTRAVENOUS INJECTION OF MERCURY.

GEORGE P. CRUME, M.D.
MINNEAPOLIS.

The hypodermic method of administering *mercury* has gained a distinct and deserved place in the therapy of syphilis. Not only has the technic been gradually improved, but preparations less irritating and better suited to our needs have been produced.

For convenience of study this method readily admits of division into subcutaneous, intramuscular and intravenous injections. It is especially to the last that I desire to call attention.

The introduction of mercury (sublimate-solution) by means of intravenous injections was first recommended by Bacelli in 1892, though other drugs had been administered in this way several years earlier. Two reasons have prevented this method from gaining more than limited favor with the profession; first, the delicacy of the technic; second, the fact that it is regarded by some, many of whom have never used it, as dangerous.

My experience with this method began about fifteen months ago and since then I have given over 200 intravenous injections, a number somewhat limited but certainly entitling one to a preliminary opinion not only as to the technic but as to the potency of the drug when thus administered.

Any preparation free from insoluble particles may be used. Solutions of bichlorid, biniodid or cyanid in 1 per cent. strength are most frequently given, the dose being from 1 to 3 c.c. repeated daily or every other day. My experience has been almost entirely with the cyanid, a salt which contains 79 per cent. of mercury and is, I believe, less irritating than the sublimate.

TECHNIC.

The technic is simple, but demands care and exactness. Almost any of the superficial veins may be used; the median basilic and cephalic are generally recommended, but I find that those on the back of the hands are most often suitable. A bandage is tightly applied proximal to the site of injection to distend and render the vein prominent. I then apply to the site for injection chemically pure alcohol on a pledget of cotton without much friction. The needle and syringe, having been prepared, may now be loaded, the needle attached and introduced almost parallel to the vein till in the lumen and in the direction of blood current. Then the bandage should be removed and the injection slowly given. When the needle is withdrawn the blood usually flows rather freely from the small puncture. This should be wiped away and no dressing applied.

Fine platino-iridium needles (2 to 3 cm. in length) should be used, and the Luer all-glass syringe is best adapted to this purpose.

It is not always easy to be certain that the eye of the needle is in the vein, though it is advised to determine this by the lessened resistance and the freedom with which the point can be moved, indications which to me are not reliable when the vein is small or located in loose cellular tissue. Using the Luer syringe, I chanced to discover that whenever the needle is in the lumen of the vein the blood at once comes into the barrel of the syringe, provided the piston is not held. This has proved in my hands a valuable aid indicative of the presence of the needle in the lumen of the vein, but it is an indication which can not be obtained unless the piston fits the cylinder so accurately that the blood pressure is sufficient to press it backward. This guards against undue wounding of the delicate endothelium, which predisposes to an endophlebitis. After the needle is in position the strictest attention is needed to keep it there until the injection is consummated. To this end an assistant is necessary to remove the bandage.

We know that syphilis is caused by a special organism, but our knowledge of the action of mercury on that organism remains purely empirical. We agree that the remedy must be absorbed, must reach the circulation, before it exerts a general effect. Then if the drug is administered by the mouth, by inunctions or intramuscular injections, there is not only the delay, which may be several days, before the circulation is reached by an amount of the drug sufficient to produce the physiologic effect, but also the greater disturbance of the system, and the increased difficulty of maintaining the desired intensity of effect. It seems to me that these disadvantages are best met and overcome by intravenous injections: that this is our best means for meeting the needs of those urgent cases in which great destruction or irreparable damage is imminent, as for example, severe visceral disease, lesions of the eye or of the nervous system. For not only can the physiologic effect be produced, but the patient's tolerance can be discovered in two or three days and with perfect safety by this method. In certain specific conditions not infrequently met this is an advantage of first importance.

OBJECTIONS.

Nevertheless, this method is not without real as well as fancied objections.

1. The technic is somewhat delicate, it being easy to miss the vein or pass the needle entirely through it.

2. Injection outside of the vein causes a cellulitis with induration at site of injection, an acute phlebitis; injection into the wall of the vein or the valves or failure to remove the bandage before injecting causes an acute endophlebitis. None of these accidents is serious, neither do they occasion much pain or inconvenience.

3. Veins are not always sufficiently prominent for the operation, especially in women and obese subjects.

4. A. Fournier asserts that it is imprudent to bring the endocardium in direct and sudden contact with a toxic agent such as mercury. But he produces no evidence and admits never having given an intravenous injection.

5. It is said that the mercury is more rapidly eliminated than by any other method and that recurrences are more frequent.

6. It is further asserted that the therapeutic effects are not very encouraging, not being, in fact, superior to those of other methods.

This last objection is not what, after careful and impartial consideration of the method, would be expected to be true, and it is not believed that experience in well-selected cases will ever establish it. That recurrences happen after treatment by this method is not denied. They occur, and often to our embarrassment, after treatment by every method; that they occur earlier than when other methods are used has not been proved, and, if it were, there would still remain a valued place for intravenous injections in the therapy of those severe conditions above indicated.

ADVANTAGES.

As a routine practice very few advise this method; as a provisory means when it is necessary to act quickly, to surprise the enemy as it were, in cases of rapidly-invading syphilis, it should receive first consideration; also as a therapeutic test; and for this purpose mercury, not the iodids, should be used in the great majority of cases. Other advantages which this method enjoys are: Absence of pain, mathematical dosage, and instantaneous introduction into the circulation.

ILEOCOLITIS WITH INTOXICATION

PRESENTING SYMPTOMS OF MENINGITIS AND FOLLOWED BY MULTIPLE NEURITIS.

H. D. McCARTY, M.D.

BALTIMORE.

History.—January 5, F. L., aged 5, had been as well as usual. At his evening meal he partook freely of canned corn, and before going to bed ate three cherry tarts. He awoke at 2 a. m., with violent pains in the abdomen, followed by nausea and vomiting. The child had a very high temperature, and before daybreak appeared somewhat delirious. The bowels were constipated. He appeared more or less stuporous, but it was not until the following Tuesday, January 9, that symptoms resembling those of meningitis developed. The family was much alarmed by the drawing back of the child's head and the occurrence of internal squint. He became even more stuporous; the tongue was thickly coated and the breath offensive, the temperature running 103-104, pulse about 120. For twenty-six days after the onset the temperature varied from 101 to 104, and the pulse was continually high. The attending physician was asked to call in a consultant, which was done, and a diagnosis of meningitis was made.

Examination.—I saw the child on January 31, at which time he presented the following picture: He was a rather large boy, extremely emaciated, with pale mucous membranes, and lemon-colored, flabby, dry skin. The patient assumed the lateral position in bed, the head was drawn back with marked rigidity of the neck and contraction of the abdominal muscles. The lower extremities were flexed on hip and knee, and all the flexors contracted and rigid. Kernig's sign was marked. The hands were clenched, arms flexed at elbow and usually held across the chest, the patient from time to time putting his hands to his mouth. The palpebral apertures were wide and equal. The pupils were dilated, equal and reacted to light sluggishly and contracted slightly to accommodation. The right eye was slightly turned in. No knee-jerk was obtained, but the contracted condition of the lower extremities made the test uncertain. Stimulation of the plantar surfaces gave plantar response. (Babinski was absent.) There was hyperesthesia of the lower extremities. Any manipulation of them evidently caused great pain. Dermographia was marked. The boy was conscious but stupid; he recognized those about him and was able to call for what he wanted. He was cognizant of pain and discomfort and called constantly for food. The presence of the father seemed to irritate the child. The child passed urine freely. The bowels were obstinately constipated. The pulse was 110 to 120, and irregular. Respirations varied in number and depth. No definite periodicity was noted. The picture was one of meningitis.

Treatment.—Being impressed after several days by the condition which had changed but little since the onset, except for the failing forces, and by the character of the stools, which were foul-smelling, dark brown in color, containing large amounts of thick jelly-like mucous, occasionally streaked with blood, decomposing clots of milk and small undigested particles of shredded wheat biscuit. I was compelled to think that the condition was possibly due to the toxins absorbed from the intestinal tract. Treatment was instituted accordingly. A large dose of castor oil was given and the bowels washed on alternate days with nitrate of silver, 1/4 gr. to the ounce, and salt solution, a long soft catheter being used. For the first week nothing but whey, albumin water, and predigested milk and brandy were given at regular intervals. One dram of bismuth in emulsion was given every twenty-four hours.

Clinical Course.—From the first the improvement was rapid and marked and the boy gained in strength and took on flesh at an astonishing rate. As the symptoms of irritation cleared up it became evident that there was a definite symmetrical paralysis of the legs. The muscles of the legs had become wasted, and there was definite weakness of the flexors of the ankle. The knee-jerk was not obtained until six weeks after improvement was first noted. The patient did not walk until about three months after improvement began. The gait was feeble, unsteady, the legs being lifted high, and the feet slapped on the ground. Examination showed the double foot drop so commonly seen in multiple neuritis. There was never any marked weakness in the arms.

It would seem from the rapid improvement following on treatment directed toward the intestinal tract that one may fairly assume that the meningeal symptoms were due surely in large part to the action of toxins and not to a definite inflammation. The involvement of the legs can be explained by the action of the poison circulating in the blood. In consideration of the admitted difficulty of the diagnosis between meningitis and the results of intestinal toxemia, this case affords great encouragement for thorough research for the primary seat of the infection, even in cases in which the outlook seems anything but favorable.

613 Park Avenue.

Regional Anesthesia by Spinal Technic.—Avramescu believes that the anesthetic injected into the spinal cavity acts on the roots, not on the spinal cord, and that consequently only those roots should be acted on which innervate the field of operation. In his communication on the subject, published in *Spitalul*, and summarized in the *Münch. med. Wchnschr.*, 1908, 2457, he states that the anesthetic should be injected between the fourth and fifth lumbar vertebræ when the operation is to be on the external genitals, perineum or anus, and between the first and second lumbar vertebræ for the inguinal region and legs. The ninth or tenth thoracic vertebræ correspond to the abdomen below the umbilicus, the sixth and seventh to the region above the umbilicus, and the first and third to the thorax. No injection should ever be made above this, on account of the danger of paralyzing the phrenic nerve.

A CASE OF ERYTHROMELALGIA.

J. P. KANOKY, M.D., and R. L. SUTTON, M.D.
KANSAS CITY, MO.

Typical examples of erythromelalgia, the "red neuralgia" first described by Dr. S. Weir Mitchell in 1872, are encountered with sufficient infrequency to merit more than passing notice.

Patient.—A. B., physician, aged 54, applied to us for treatment on July 1, 1908.

History.—He is a native of Prussia, having removed to America in 1887. He has had one attack of gonorrhea, over thirty years ago, but has never had syphilis. There is no history of any serious illness, although he has been a frequent sufferer from slight attacks of rheumatism and has for many years been subject to neurasthenia. His circulation has always been good. He has never sustained an injury of any kind and has never indulged in violent exercise or experienced prolonged physical fatigue. Formerly he was a moderate drinker of beer, but for the past ten years he has been an abstainer. He averages one cigar a day. In June, 1908, his wife, who has always been an invalid, had a stroke of apoplexy, with resulting partial paralysis. For a considerable period the husband was with her constantly, day and night, and this nervous strain, together with the loss of sleep and his susceptibility to neurasthenia, came near resulting in a mental breakdown.

Present Illness.—It was at this time he first noticed an irregular, rosy to dark red mottling of both palms, including the palmar surfaces of the thumbs and fingers, with some swelling and slight elevation of temperature. This was especially marked if the arms were allowed to hang at the sides. When the hands were held over the head the redness slowly disappeared, although the puffy condition of the tissues persisted for several hours. About one week after this he experienced a severe attack of neuralgia. The pain, which was burning and stinging in character, "as if a puff-ball made of red-hot needles had been forcibly grasped," affected both palms, came on suddenly, and lasted for about thirty minutes. Since that time he has had an attack almost daily, the paroxysm lasting from a few minutes to an hour. The only local application that gave any relief was cool water, and its effect was only transitory. Hot or cold water increased the pain.

Examination.—Both palms were found to be slightly swollen (the patient had had an attack fourteen hours previously) and a trifle paler than normal. There was no pain, although the parts were extremely sensitive to the touch. There was no pitting on pressure. Compass points separated by a distance of 1 cm. could be readily distinguished in the centers of both palms. Sensibility to both heat and cold was increased. There was no atrophy or loss of motion in either limb, and no tenderness over the nerve trunks. The reaction of degeneration was not present. The skin was normal, so far as could be ascertained with a high-power hand-glass. The patient was in constant fear, however, of becoming infected through some skin abrasion and frequently thought he had found cracks in the epidermis where, in reality, the integument was smooth and unbroken. Both pupils were normal and reacted readily to light. Urine examination was negative. The knee-jerks on both sides were exaggerated and the ankle-jerks a trifle excessive. The blood pressure was 128 mm. (Riva-Rocci, 14 cm. armlet, recumbent posture). The radial arteries were softer than is usual in a man of 54. When seen on the following day the patient was in the midst of an attack and appeared to be suffering intense pain. The palms were deep red in color and, especially those portions overlying the metacarpo-phalangeal articulations, greatly swollen. The parts were much more sensitive than at the first examination, the slightest pressure giving rise to increased suffering. Manipulation of the limbs or pressure over the nerve trunks did not increase the pain.

Course of Disease.—Since then we have seen him many times while in the course of an attack, the symptoms being practically the same in every instance. Worry, either as a result of his wife's condition or as to his own future, and excessively hot weather both have a tendency to increase the frequency as well as the severity of the paroxysms. On August 24 he endeavored to turn a tight water faucet with his right hand. Considerable force was used, the greater part of the pressure being borne by the ball of the right thumb. A few hours afterward the thumb became red, swollen and extremely painful. The edema persisted for forty-eight hours, then gradually subsided. Three days later a superficial exfoliation of the overlying skin began and, during the following week, the entire palmar surface of the thumb shelled off, being replaced by apparently healthy epidermis. On September 15 it was noticed that the outer layers of this new skin had become cracked and broken and, although signs of inflammation were absent, a second exfoliation occurred. On October 10 several small papules could be seen beneath the epidermis of the right palm. Five or six reached the surface, vesiculated and scaled off, having given rise to practically no subjective symptoms. The patient has now been free from severe neuralgic attacks for over two months, although there is considerable congestion and some pain manifested when the arms are allowed to hang naturally at the sides for an hour or more. His general health is much improved, because, in large measure, of the return of cooler weather.

Treatment.—Of the numerous therapeutic agents tried in this case only three have proved of perceptible value: lecithin, as a tonic; aspirin, given for its antirheumatic effect and empirically to alleviate the condition; and the *x*-rays, employed because of their action on the peripheral nerve endings. The exposures, which were brief (from three to five minutes, on alternate days, a soft tube, at 15 cm. distance, being used), appeared to give more relief than any other measure applied.

276 Ridge Building.

POSTCLIMACTERIC UTERINE HEMORRHAGE, DUE TO RELATIVE HYPOTHYROIDISM.

C. C. WALLIN, M.D.
LEWISTOWN, MONT.

Physiologic antagonism between the secretions of the ovaries and thyroid has, for some time, been in a general way recognized. Bandler very definitely attributes many of the nervous symptoms arising in adolescence and in the climacterium to "relative hyperthyroidism," by which is signified a failure of the ovaries to produce sufficient of their internal secretion to neutralize the entire product of the thyroid. Thus a condition similar to Basedow's disease is brought about, which condition is relieved by the administration of ovarin.

That the normal balance between the secretions of the thyroid and ovaries may be disturbed by a deficient thyroid secretion, thus bringing about a relative hyperthyroidism, which may be the cause of uterine hemorrhage, I have not seen stated in any of the literature at my command. The following case demonstrates that such a condition may arise:

Patient.—Mrs. D., aged 55. Early history uneventful. Menses were established normally at 14 years, and were regular and painless until the age of 38. The patient had four children, all the labors being normal and without instrumental aid.

Present Illness.—When the patient was 38 menstruation ceased for several months, since which time it had been irregular in periodicity and quantity, the flow occurring at intervals of from two to seven months, and being accompanied by a sense of constriction in the throat and some visible enlargement of the thyroid, together with general nervousness. When first seen by me in April, 1908, the patient had been "feeling bad" for several days, and for the two days previous had been flowing more than usual, yet was not sick enough to go to bed. This meeting was rather casual and she was advised to keep off her feet and rest for a day or two. After two days the flow was unabated, the general nervous condition worse, and the thyroid gland decidedly enlarged.

Treatment.—Thyroid extract was administered in doses of two grains three times daily, and at the end of the twenty-four hours following the flow had ceased and the swelling of the thyroid was perceptibly diminished. After twelve doses the size of the gland was normal. Since this experience the patient keeps a supply of thyroid on hand, and when she feels an exacerbation of nervous symptoms, with constriction of the throat and pelvic congestion, takes a few doses and is relieved.

The results obtained are satisfactorily explained only by recognizing the antagonistic influence of the secretions of the glands mentioned. It has long been known that certain enlargements of the thyroid are due to a deficiency in its proper secretion. The rôle of the ovarian secretion in causing congestion of the pelvic organs, thus aiding in bringing about the menstrual flow, is a somewhat later conception. In the foregoing case thyroid insufficiency is evidenced by the enlargement of the gland. The uterine hemorrhage is attributable to the action of that portion of the proper ovarian secretion which was not neutralized, owing to the deficient thyroid product. By treatment which supplied the lacking thyroid substance the normal balance was restored, the relative excess of the ovarian secretion was neutralized, and the pelvic congestion and consequent hemorrhage checked. On the thyroid the usual action of reduction in size was obtained as in the type of goiter alluded to.

Therapeutics

ASTHMA.

In the first place, the disease asthma should be dissociated from conditions which are termed asthmatic. A patient may be asthmatic from various causes, but the term asthma should be limited to the disease or condition itself, i. e., periodic attacks of bronchial spasm. More or less continued dyspnea, with or without whistling râles, and with or without acute attacks of asthma, may be caused by cardiac disease, cardiac asthma; by renal insufficiency, renal asthma; by plethora, causing attacks of acute hyperemia of the lungs; by arteriosclerosis; emphysema; diabetes; thyroid disturbances, and by the various anemias. Spasmodic asthma may be caused by bad heart attacks; by acute toxemia from renal insufficiency; by exacerbations of gout, probably due to a toxemia from nitrogenous mal-metabolism; by acute indigestion, and by gastrointestinal irritants causing a swelling of the mucous membranes of the bronchial tubes, really an urticaria. This swelling of the mucous membrane of the bronchial tubes has been caused by diphtheria antitoxin.

The diseased condition, or neurosis, termed true asthma, is often due to irritation of the nose and throat, and sometimes of the ear; is frequently due to chronic bronchitis, often is concomitant with acute disturbances of the mucous membranes of the upper air passages, as when caused by irritations from pollen, such as hay fever, rose fever, and by various dust and drug irritants. Asthma, however, is frequently a neurosis alone, not being caused by any one particular condition or irritation. This is pure "cussed" asthma and has been termed the "epilepsy of the lungs." Probably these unexplained attacks of asthma are caused by some irritant in the blood similar to the exciting cause of an epileptic attack. Such irritations being removed or prevented, the frequency of the attacks will be diminished. However, like epilepsy and like migraine, a habit of asthma having been formed, even after the early exciting cause has been removed, the nervous centers having become accustomed to the periodic discharge of excessive energy, will often continue this vicious habit. Consequently, like a beginning *petit mal*, and like a beginning eyestrain headache, little mild recurrent attacks of asthma should be inhibited, if possible, at the beginning, lest the patient be condemned to suffer for years, or a lifetime, from recurrences of this terrible condition of real asthma.

An attack of asthma generally occurs at night, and may be preceded by headache, some symptom of indigestion, mental depression or nervous irritability. There is at first some slight dyspnea and a short dry cough. The dyspnea and consequent cardiac distress increase, and the agony suffered by these patients can not be understood unless one has seen them suffering from an attack of this terrible disease. The agony is almost as great as that of acute cardiac dyspnea, although there is not so much mental anxiety. The patient may be pale or almost livid, and the expression of the face shows the suffering due to attempts to inspire, and then to expire, through the contracted bronchial tubes. The muscles of inspiration being stronger than the muscles of expiration, for a time more air enters the lungs than can get out, and little by little there is increased chest distention. Percussion shows hyper-resonance. The greatest amount of wheezing, as shown by the stethoscope, is in expiration, and the expiration is prolonged in the attempt to empty the lungs and prepare them for the next inspiration. If the bronchial secretion begins, as it generally does, moist râles may also be heard, and, after a series of spasmodic efforts, the cough brings up white glairy mucus.

The pathology of the condition is a spasm of the bronchial tubes. To what distance and to how small bronchi this spasm extends can not be well decided. No one should contend that the mucous membrane of the bronchial tubes may not suddenly swell and this swelling alone, obstructing the passage of air into the deeper portions of the lungs, cause an asthma. Such is doubtless the condition in certain poisonings by drugs that cause urticaria and in the rare instances of antitoxin poisoning. Also it is not only probable but a fact that sooner or later in an attack of asthma the mucous membranes become more or less congested from the upset condition of the usual differences in the pressure within the lungs or without the lungs, which is so readily understood if one recognizes that the right side of the heart has lost its aid from the usual negative pressure in the lungs. This congestion of mucous membranes, of course, soon means exudate, and exudate means more or less mucous and watery secretion. But this is only an incident in ordinary asthma, the spasmodic contraction of the bronchi is the cause. This is not true of the asthmatic conditions caused by circulatory disturbances. Such asthma may be caused more by sudden hyperemia of the mucous membrane of the lungs than by the spasmodic contractions, but true asthma is as above described.

During the attack little rice-like particles, which are white and gelatinous, are often coughed up and have been called *"perles"* of Laennec. These little pellets may sometimes be unfolded, as first described by von Curschmann, into little spiral strings of mucin, some of which may be wrapped around a globule of mucin. These *perles* probably originate in the smaller bronchial tubes. Sometimes, also, sharp octahedral crystals are found in the expectorated matter. These are known as Leyden's or Charcot's crystals. Whether or not in certain patients these crystals, or these pellets, of mucin are the cause of the attack of asthma has not yet been determined, but some patients are more or less asthmatic as long as these little affairs or objects are found in the sputum. When they are no longer present the cough ceases, the little bronchitis which the patient has had ceases, and the asthma may be absent for a shorter or longer period of time; then a recurrence of the condition generally takes place. If the blood is examined during the attack or shortly after, frequently a greatly increased number of eosinophiles are found. This would seem to denote gastrointestinal irritation.

The length of these attacks of acute asthma, if unrelieved, varies from an hour or two to all night, and sometimes an attack may last several days. Occasionally the attacks last for many hours, or even days, in spite of all treatment, and any temporary relief given by powerful drugs may not prevent the resumption of the asthmatic spasm the moment the patient is out of the influence of the drug. The amount of dyspnea that the patient has, and the amount of suffering and the seriousness of the attack, do not bear a close relation to the amount of wheezing that is heard. A patient may not suffer greatly from dyspnea so long as he is sitting upright, and yet be wheezing like a decrepit old horse.

The longer the paroxysm lasts and the more intense it is the greater the danger of permanent injury to the heart and the greater the danger of the distention of the chest, so injuring the lung tissue as to make the emphysema permanent. Even after repeated attacks most patients have no cardiac injury and no lung injury, but this is doubtless because most of those who suffer from acute asthma are young; the older patients do have more or less lasting bronchitis, heart debility and more or less constant dyspnea and often emphysema. It is rare for a patient to die during an attack of acute asthma, but the condition should always be considered serious, as it could never be decided how much future disability was caused by the prolongation or repetition of such serious disturbance of the vital functions of respiration and circulation.

Acute attacks of asthma may occur every night for a series of nights, and then not for a long period, or after one attack there may be no more for some time, or they may occur more or less periodically, or they may recur only at certain periods of the year or in certain places. These last are likely to be due to nasal irritations. The attacks may also occur more or less frequently for several years, or even for a lifetime.

The treatment of this troublesome disease, or condition, will never be a success unless the cause has been determined, and, if possible, removed. Hardly any patient with any disease should receive a more careful general examination than the asthma patient. The lungs must be carefully examined for bronchitis and emphysema, and more serious conditions found or eliminated, and the blood pressure taken. The digestive ability of the stomach and intestines should be investigated, the urine should be examined, and all possible reflex causes sought in the throat, nose or ears. If all tangible causes of the asthmatic attacks have been eliminated, a careful analysis of the excretion of the various salts and solids in the twenty-four hours' urine, on a known diet, should be made. Even careful examinations of the feces, on a known diet, may give conclusive evidence of the cause of the toxemias that give rise to asthma. So much for negative evidence.

Positively, asthma is caused by polyps in the nostrils, hypersensitive mucous membrane in the nostrils, hypertrophy of the Schneiderian mucous membrane, adenoid conditions of the nasopharynx, lingual tonsil irritations, and tonsil irritations and concretions, by growths or irritations in the larynx, chronic bronchitis, emphysema, insufficiency of the right side of the heart due to various cardiac lesions, arteriosclerosis, hyperacidity of the stomach, intestinal sluggishness and the absorption of toxins therefrom, insufficient urine excretion, amenorrhea, hypothyroidism, i. e., insufficiency of the thyroid, gout, diabetes, and uremia. Asthma also occurs when no amount of investigation can discover a cause other than the intangible condition of a neurosis.

Certainly, the cause being ascertained, the prevention of the action of that cause, if possible, is the height of the scientific treatment of asthma, and it is obviously unwise and unscientific to give all kinds of recommended drugs for the prevention of asthma when the etiologic factor has not been determined, and, finally, by a long process of trying one drug after another, find something that will, perhaps, benefit the patient. Such treatment is just as obsolete as is the administration of large doses of quinin in continued fever, and if the quinin does not prevent the progress of the disease, decide that the fever is typhoid.

Perhaps the most frequently successful drug in preventing the recurrence of asthma is an iodid, and this is probably because most asthma is due to affections of the air passages, and this drug is specifically a stimulant to the mucous membrane of the nose, throat and bronchial tubes. If any chronic disturbance is located in these mucous membranes the iodid tends, first, to increase the exudate from these membranes, then to make the mucus more liquid, and, while at first apparently irritant, soon relieves congestion of these membranes, and often, sooner or later, cures a chronic congestion and causes the membrane to become healthy. Hence the frequency of success from iodid simply emphasizes the necessity of a careful examination for, and the removal, if found, of any nasal obstructions or irritations. After such removal, a sensible treatment to prevent the recurrence of attacks would be the prolonged administration of iodids, and very large doses are seldom needed, or if the history of the attack shows long standing of the disease, the treatment of the neurosis by bromids is advisable, and here again the dose should not be large. We should not produce debility either with iodid or with bromids.

The patient under the administration of either drug should be carefully watched, and if no weight is lost and the digestion is good, we may continue such treatment for some time, gradually reducing the drug as the attacks of asthma are inhibited. For the prolonged use of either iodids or bromids the sodium salts are the best, as sodium does not cause muscle debility and is not poisonous to living tissues, as is potassium. In asthma due to chronic bronchitis, and in asthma with but little bronchitis, but with the repeated expectoration of the round gelatinous particles, the prolonged use of iodids seems to have the best curative effect.

Arsenic, a so-called alterative drug, seems at times to have a specific action on the organs of respiration. In chronic bronchitis, in asthma, and in catarrhal conditions of the air passages, arsenic, when given for a long period, is sometimes of considerable benefit. The respiratory ability and freedom from colds and coughs of the arsenic eaters of France and the Alps is well known.

A local cause in the upper air passages having been removed, if there was any such, besides treatment either by iodids or bromids, if either one is deemed advisable, anything that will improve the general health of the individual should be utilized. An occupation in which there is an atmosphere of dust or other irritant should be changed for one more suitable. Perhaps indoor work should be changed for outdoor work, perhaps the climate or location should be changed. Any indigestion, gastric or intestinal, should be corrected; constipation should be prevented; anemia should be treated, and insufficiency of the thyroid, if present, should be noted and modified.

If asthma recurs at certain periods of the year as does hay fever, the preventive treatment is the same as for hay fever. Anything that will reduce the nasal irritations and congestions will relieve the asthma, and any change in location that will prevent the hay fever will generally prevent the asthma. To just what locality or climate an asthmatic patient should be sent is difficult to determine. Also, it is impossible to predict that, because one patient is benefited by a sojourn or residence at one particular place, that place will be beneficial to the next patient. Theoretically, regions free from dust and vegetation should be the regions to prevent attacks of asthma. Sea voyages are sometimes beneficial and sometimes not. The decision as to whether or not benefit will be derived from certain regions may often be determined by a careful investigation into the condition of the patient's mucous membranes and the condition of his circulation.

Anything that would tend to make the circulation better in the mucous membranes of the upper air passages and diminish congestion and tumefaction of the mucous membranes of all the air passages will tend to prevent recurrences of asthma. Cardiac insufficiency, of course, should be properly treated, and whether the heart needs digitalis or the arteries need nitroglycerin or nitrites continuously, or whether the general good effect of ergot on the circulation is needed (and asthma may sometimes be prevented by ergot) must be determined by a careful study of the individual patient.

Insufficiency of the kidneys as a cause of asthma should be treated by the proper diet and the prevention, if possible, of nitrogenous toxemias. Such asthma is an indication of nitrogenous poisoning. The asthma due to gout is often best combated with thyroid, and when there is insufficiency of the thyroid in young individuals, which may be recognized by well-known signs, such as amenorrhea or scanty menstruation in women, an unusual and undesirable increase of fat, a dry condition of the skin, and a tendency to nitrogenous poisonings, the asthma will be benefited by small doses of thyroid, perhaps, coincidentally administered with small doses of iodid, as iodid has been shown to be the most active stimulant of the thyroid gland.

New and Nonofficial Remedies

THE FOLLOWING ARTICLES HAVE BEEN TENTATIVELY ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR INCLUSION IN THE PROPOSED ANNUAL, "NEW AND NONOFFICIAL REMEDIES." THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT, BUT TO SOME EXTENT ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE FINAL ACCEPTANCE AND PUBLICATION IN BOOK FORM.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(A list of all accepted articles is published on an advertising page of THE JOURNAL *in the first issue of each month.*

(Continued from Vol. LI, page 1513.

BILE SALTS.[1]

The bile of man and of several animals contains in varying proportions the sodium salts of conjugated cholic acids; in ox and human bile especially glycocholate acid $C_{26}H_{43}O_6N$: and taurocholic acid, $C_{26}H_{45}O_7NS$. Fresh ox gall is said to contain about 3 per cent. each of sodium glycocholate and sodium taurocholate.

The sodium glycocholate and taurocholate may be separated in the following manner: Dry ox bile is treated with absolute alcohol and the tincture precipitated by ether in excess. Both salts are deposited and the glycocholate crystalizes upon standing, the taurocholate remaining in amphorous form, resembling oily or resinous matter. If the deposit is dissolved in water, solution of lead acetate will throw down a lead glycocholate, while the addition of lead subacetate to the remainder will precipitate the taurocholate (U. S. Dispensatory, p. 490).

Tests: All the bile acids respond to Pettenkofer's test. A small portion of the salt is dissolved in a little concentrated sulphuric acid in a small porcelain dish and warmed, care being taken that the temperaure does not rise higher than 60° to 70° C. A 10 per cent. solution of cane sugar is then added drop by drop while the liquid is stirred with a glass rod. If compounds of cholic acid are present a beautiful red color will appear, which does not disappear at room temperature, but usually in the course of a day becomes bluish violet. The red liquid shows in the spectrum two absorption bands, one at F and the other between D and E near to E. Care must be taken not to heat too much nor to add too much sugar. The sulphuric acid must be free from sulphurous acid and the lower oxides of nitrogen. As albumin, oleic acid, amyl alcohol, morphine, etc., may give a similar reaction, spectroscopic examination should not be omitted in doubtful cases (Hammarsten, Lehrbuch der physiolog. Chemie, p. 312).

Furfurol Test (Mylius): The substance is dissolved in alcohol and for every one cubic centimeter of the alcoholic solution, one drop of a 1:1000 furfurol solution and one Cc. of concentrated sulphuric acid are added and the mixture cooled, if necessary, so that the temperature may not rise too high. The same color reaction occurs as in Pettenkofer's test.

Actions and Uses.—The bile salts constitute the main active principles of bile, and therefore share the actions and uses of the latter, perhaps with the advantage of more constant composition. When injected into the circulation they cause severe nervous and cardiac depression, not observed when they are given by mouth. They are generally credited with a slight antiseptic and laxative action, with enhancing the efficiency of the resinous hydrogogue cathartics, and with emulsifying and hence favoring the absorption of fat. They stimulate the secretory activity of the liver, increasing both the fluids and solids of the bile; indeed, they are the most powerful, if not the only, cholagogues known.

They may be used in obstructive jaundice, although the rationale is somewhat doubtful; their use in biliary fistula is more reasonable, if the nutrition is noticeably affected.

BISMUTH AND IRON CITRATE (SOLUBLE) Wellcome Brand—Bismuthi et Ferri Citras, Wellcome.—A "scale salt" containing bismuth citrate and ferric citrate in amounts corresponding to from 38 to 40 per cent. each of the respective anhydrous salts (corresponding to 20 to 21 per cent. bismuth and 8.7 to 9.1 per cent. iron) the combination being rendered soluble in water by means of ammonia.

Bismuth and iron citrate (soluble) occurs in yellowish-green scales, readily soluble in water, having a saline, mildly ferruginous taste.

---

[1] Under the general heading the several bile derivatives accepted for N. N. R. will be described.

A solution of bismuth and iron citrate (soluble) is acid toward litmus; addition of dilute acids or of ammonia water renders the solution darker but does not cause precipitation; addition of sodium hydroxide T S causes formation of a reddish brown precipitate and evolution of ammonia

The iron content of bismuth and iron citrate soluble may be determined by the methods prescribed for ferri et ammonii citras U S P The amount of bismuth is determined by precipitating by hydrogen sulphide from an acid solution dissolving the bismuth sulphide obtained in dilute nitric acid, precipitating the bismuth from this solution by ammonium carbonate and weighing as bismuth oxide

Actions and Uses—It has the properties of iron and soluble bismuth salts Its administration is recommended when dyspepsia accompanies anemia when the sedative action of bismuth is exerted on the digestive organs, while the iron produces its effects.

Dosage—0.3 to 0.65 Gm. (5 to 10 grains).

Manufactured by Burroughs Wellcome & Co, London and New York Not patented or trade marked

ERGOTININE CITRATE—Ergotininæ Citras —The citrate of ergotinine, a crystalline alkaloid, probably $C_{35}H_{39}O_5N_5$, (Barger and Carr) derived from ergot

Ergotinine is obtained by extracting the residue left on evaporation of an alcoholic tincture of ergot with light petroleum to remove oily matter, dissolving the residue in ethyl acetate and shaking with citric acid solution Sodium bromide or hydrobromic acid is then added and the precipitated hydrobromides of the alkaloids, ergotinine and ergotoxin are collected The mixed hydrobromides are dissolved in caustic soda and shaken with ether, in this way ergotinine is removed first Finally, the ergotinine is crystallized from alcohol leaving ergotoxine and impurities in the mother liquor By interaction of ergotinine with citric acid, ergotinine citrate is obtained

Ergotinine citrate is a grayish-white amorphous powder, slowly soluble in water, it has an acid reaction to litmus paper

Ergotinine crystallizes in long needles the sides of which are not quite parallel, which darken and melt at temperatures from 219° to 229° C One part of ergotinine dissolves at 18° in 292 parts of alcohol, 1020 parts of absolute ether, in 91 parts of ethyl acetate, and is moderately soluble in acetone and benzene, and readily soluble in chloroform It is insoluble in light petroleum and in water Its specific rotation in alcoholic solution saturated in the cold is + 338° It forms salts which produce colloidal solutions in water which are precipitated by electrolytes so that they are little soluble in the presence of the stronger mineral acids

Tests. Ergotinine citrate when carefully decomposed by alkali the mixture extracted with ether and the ether evaporated yields a residue which responds to the test for ergotinine Solutions of ergotinine have a bluish violet fluorescence especially when acidified Concentrated sulphuric acid colors the alkaloid at first yellow, after some hours violet and at length blue If a small quantity of ergotinine is dissolved in concentrated sulphuric acid and a trace of ferric chloride added the mixture takes on an orange red coloration, which soon passes into red while the edges of the liquid are colored blue or bluish green

If a few milligrams of ergotinine are dissolved in about 4 Cc of glacial acetic acid a trace of ferric chloride added and the mixture underlaid with concentrated sulphuric acid a beautiful violet color appears at the junction of the two liquids

Actions and Uses—According to the investigations of Barger and Dale ergotinine has very slight physiologic activity when it enters the system unchanged, but it is liable to be converted to a certain extent into ergotoxine, which possesses marked physiologic activity and appears to represent the pharmacologic actions of ergot The action of ergotinine when given per os or when injected hypodermically, is variable in intensity but represents the action of ergot

Ergotinine citrate can be used as a substitute for ergot, and is said to act efficiently, when injected hypodermically, in the treatment of headaches and of uterine hemorrhage. Combined with strychnine it is said to be useful as a stimulant in uterine hemorrhage

Dosage.—.00033 to .00066 Gm (1/200 to 1/100 grain), hypodermically

Proprietary Preparations:

TABLOID ERGOTININE CITRATE—Tabloida Ergotininæ Citratis—Each tablet contains ergotinine citrate 0.00033 Gm (1/200 grain)

Dosage.—One or two hypodermically

Prepared by Burroughs Wellcome Co London and New York U. S Trademark on Tabloid Nos 11,993, 43,563, 43,559, 43,569; 44,219

TABLOID ERGOTININE CITRATE AND STRYCHNINE SULPHATE—Tabloida Ergotininæ Citratis et Strychninæ Sulphatis—Each tablet contains ergotinine citrate 0.00065 Gm (1/100 grain) and strychnine sulphate 0.0033 Gm. (1/20 grain).

Dosage—One or two hypodermically.

Prepared by Burroughs Wellcome Co, London and New York U. S trademark, as for Tabloid Ergotinine Citrate.

FLUORESCEIN—Fluoresceinum.—Resorcinolphthalein (a term not strictly correct but commonly used), dioxyfluoran—Fluorescein, $O{:}(C_6H_3OH)_2{:}\overline{C\,C_6H_4.COO} = C_{20}H_{12}O_5$, is the anhydride of fluoresceinic acid $O{:}(C_6H_3OH)_2{:}C(OH).C_6H_4(COOH) = C_{20}H_{14}O_6$

Fluorescein is prepared by the fusion of phthalic anhydride and resorcinol at 195-200° C (383-392° F) till the mass becomes solid This is extracted with water and the residue dissolved in potassium hydroxide solution which is then filtered and the fluorescein precipitated with acid

Fluorescein is an orange red powder, insoluble in water, ether, chloroform and benzol soluble in hot glacial acetic acid and boiling alcohol It dissolves in alkaline solutions with formation of a salt

The alkaline solution by transmitted light is red, by reflected light it has a green fluorescence even in very dilute solutions When fluorescein is boiled, with chalk and water, the calcium salt of fluorescein is formed which is recognized by its red brown color and green sheen

Actions and Uses.—The soluble sodium salt of fluorescein (fluorescein 2 Gm, sodium bicarbonate 3 Gm, water to make 100 Cc) has been used for the diagnosis of corneal lesions and detection of minute foreign bodies imbedded in the cornea. While a weak solution of fluorescein will not stain the normal cornea, *ulcers or parts deprived of epithelium will become* green and remain so for a time; foreign bodies will appear surrounded by a green ring; loss of substance in the conjunctiva is indicated by a yellow hue Fluorescein also reveals defects of the endothelium of the cornea and produces a deep coloration of the cornea if the endothelium is absent or diseased

Non Proprietary Preparation·

TABLOID (OPHTHALMIC) FLUORESCEIN B.-W. & CO.

Each tablet contains 0.00026 Gm (1/250 grain) fluorescein in combination with sodium, and weighs 0.0032 Gm. (1/20 grain) Prepared by Burroughs Wellcome & Co, London and New York.

QUASSIN—Quassinum.—A bitter principle found in quassia.

The alcoholic extract of Jamaica quassia wood (Quassia U S P) is neutralized with magnesia then acidified with tartaric acid and the alcohol distilled off The residue is shaken up with chloroform and the solution evaporated to syrupy consistency and dissolved in a mixture of equal parts of absolute alcohol and ether This solution is evaporated and the residue dissolved in as little absolute alcohol as possible, the solution covered with a layer of ether and allowed to evaporate The crystals which form are recrystallized from alcohol The product thus prepared consists of two bitter principles α picrasmin ($C_{35}H_{46}O_{10}$) melting at 204° C (399.2° F.) and β—picrasmin ($C_{35}H_{46}O_{10}$) melting at 209-212° C (408.2—413.6° F)

Quassin crystallizes in oblique rhomboidal needles with a pearly lustre It is odorless but has a bitter taste Its melting point is 210° C (410° F) and cooling it forms an amorphous mass It is soluble in about 400 parts of water at 15° C (59° F); in 30 parts alcohol (85 per cent) and in 21 parts of cold chloroform. It is very soluble in boiling alcohol in acetic acid, and very slightly soluble in ethyl and petroleum ethers It is soluble in concentrated acids and alkalies but not in alkaline carbonates Continued action of alkalies forms resins (Pharm Francaise, 1908) It is dextrorotatory in its chloroform solution 4.22 gm. in 100 Cc chloroform rotating the plane of polarized light to the right with a specific rotation of plus 38° 8′ Solutions of quassin are neutral

It dissolves to a colorless solution in concentrated sulphuric acid, which becomes red on the addition of sugar. (Pharm Francaise, 1908)

Actions, Uses and Dosage—Bitter stomachic, 0.002 to 0.02 Gm (1/30 to 1/3 grain) before meals

Quassin (amorphous) is not identical with the above and should not be confounded with it.

POTASSIUM MERCURIC-IODIDE—Potassii Hydrargyroiodidum.—A complex salt formed by interaction of mercuric iodide with potassium iodide

When mercuric iodide is added to an excess of potassium iodide solution a colorless liquid is obtained containing the mercuric iodide as a complex salt approximately K_2HgI_4 (or $2KI+HgI_2$). Under suitable conditions (Naylor and Chappel Pharm J, Mar 7 1908 p 315) the salt having the composition $K_2HgI_4+3H_2O$ (or $2KI+HgI_2+3H_2O$) may be obtained in yellow needle shaped crystals

Potassium mercuric iodide is deliquescent and is decomposed by water

Actions and Uses—The same as mercuric iodide, over which it is claimed to have some advantages because of its solubility.

Proprietary Preparation·

SOLOID MERCURIC POTASSIUM IODIDE.

Tablets said to contain in each tablet mercuric potassium iodide (potassium mercuric iodide) ($HgI_2.2KI=K_2HgI_4$) 0.113 Gm (1.75 grains), an excess of potassium iodide which prevents the decomposition of the potassium mercuric iodide when water is added and a trace of coloring matter

Prepared by Burroughs Wellcome & Co, London and New York

SATURDAY, DECEMBER 19, 1908.

HEMOLYSIS IN CANCER.

It has long been a matter of common belief that the grave anemia and cachexia occurring in so many cases of cancer can not always be explained by the mere mechanical action of the tumor. Bard,[1] in 1901, having observed the frequent occurrence of hemolysis of corpuscles in cancerous pleural effusions, suggested that such hemolysis might well constitute a factor in the production of the cancerous cachexia. In recent years efforts have been made to clear up this matter of the toxicity of cancer by experiments; and the results, while still incomplete, are worthy of consideration, particularly those dealing with the hemolytic properties of tumor extracts and of the serum of sufferers from cancer.

The results obtained with tumor extracts with practical uniformity show the existence in them of hemolytic substances. Some investigators report positive results in all their cases, others in a considerable proportion. Weil[2] recently found no essential differences, beyond one of degree, between the extracts of non-necrotic tumors and those of certain normal organ extracts which have been known for some time to possess hemolytic powers. Necrotic tumors, however, yield a far more actively hemolytic extract, which differs from that of the non-necrotic tissues in greater simplicity of composition and probably also in stability to heat.

Of the contributions to the study of isohemolysis by serum of cancer patients, two of the most important are by Weil and Crile. Weil[3] attacked this phase of the subject by experiments on inoculable lymphosarcoma of dogs. He found that both the serum and the corpuscles of animals suffering from these tumors manifested departures from the normal, the former becoming distinctly more hemolytic, the latter more resistant to hemolysis. In cases of human cancer, however, he was not able to get such striking results. Forty per cent. (6 cases) of early and 56 per cent. (9 cases) of his cases of advanced cancer showed similar changes to those obtained in dogs with lymphosarcoma. He obtained a similar result in 1 of 3 cases of benign tumor, also in 11 of 43 cases of other diseases. He concludes therefore that the change can not be considered as pathognomonic of malignant disease, although he admits that it is much more frequently found here *than in any other condition.*

The results of Crile's[4] work, on the other hand, point more strongly toward the specificity of the reaction. He obtained isohemolysis in 130 of 153 cases of cancer, and this for the most part early in the disease; and hemolysis in 55 of 123 cases of miscellaneous diseases, including 48 of 52 cases of tuberculosis. Crile *states, however, that the reaction of tuberculosis differs* from that of cancer in that in the former cases normal serum hemolyzed the patients' corpuscles; this did not occur with cancer. With 211 normal individuals the results were negative.

Other observers, in the main, report less satisfactory results. Rosenbaum,[5] using the corpuscles of various animals, obtained positive results in 54 cent. of the carcinoma cases he tested. Kelling,[6] likewise using animal corpuscles, obtained hemolysis in 119 out of 265 cases of cancer, and in only 11 of 320 cases of other diseases. It is of interest that he obtained negative results in several cases of cancer of the pylorus, some of which later showed hemolytic activity after improvement in general condition following gastroenterostomy. This agrees with the fact observed by Crile that negative results not infrequently are obtained in cases of advanced cancer. More recently Fischel,[7] using Kelling's technic, obtained positive reactions in 2 of 4 cancer cases, but also in several cases of various other diseases.

It is evident from the foregoing that it is too early to ascribe an unqualified diagnostic value to the occurrence of hemolysis in cancer. The work, however, is of value in elucidating the phenomena of anemia and cachexia in cancer, and further investigation, with improvement in method and technic, may some day give us in the hemolytic power of the serum of cancerous patients a diagnostic reaction of great value.

THE HARD PALATE IN NORMAL AND FEEBLE-*MINDED* INDIVIDUALS.

The conclusion that idiocy and degeneracy are especially marked by deformities of the palate has been widely accepted. This proposition was sustained by Dr. J. L. Down, who was at the head of Earlswood Asylum for the Feeble-Minded in England. By measurement he found a narrow and high palate so common that he concluded that these characteristics were peculiar to persons imperfectly developed intellectually. That there was some reason to doubt this conclusion was shown by N. W. Kingsley, an American dentist, who took the pains to re-examine the mouths on which Dr. Down had based his conclusions. In a *paper published* in 1875 Kingsley said: "About 2 per. cent. might be said to be pronounced cases of narrowed or V-shaped arches, and another 5 to 10 per cent. might be said to have more or less tendency in that direction; but of the more positive cases I did not see one so marked as I have seen and treated in private practice and associated with full intellectual development."

---

[6] Berl. klin. Wchnschr., 1907, xliv, 1355.

[7] Berl. klin. Wchnschr., 1908, xlv, 882.

The refutation by Dr. Kingsley failed, however, to be received as final, and investigation by other workers seemed to sustain the opinion of Dr. Down. The theory of stigmata of degeneracy became popular, and it was generally accepted that the narrow and high palate was one of the stigmata. Dr. Walter Channing undertook to investigate the subject and in 1897 published his results, arriving at the following conclusions:

1. Two-fifths of the palates of idiots are of fairly good shape. 2. Palates of normal individuals may be deformed. 3. The difference between the palates of idiots and those of normal individuals is one of degree and not of kind. 4. In either case deformity of the palate shows irregular development anatomically. 5 Palates of average children and those of idiots, under 8 years of age, probably do not in the majority of cases differ markedly. 6. There is no form of palate peculiar to idiocy. 7. The statement that a V-shaped or other variety of palate is a stigma of degeneracy remains to be proved.

To test this matter more fully, Channing and Wissler[1] have measured a large number of casts of the mouths of both normal and pathologic individuals, using the principles of anthropometry. They attempt to distinguish by mathematical formulas and statistical tables between differences due to real and those due to accidental variations. Exact measurements are made to take the place of mere inspection, a quantitative method being substituted for the ordinary qualitative one.

The results of the examination show a slight difference in degree but not in the kind of variability between the normal and the feeble-minded. While the palates of the feeble-minded exhibit somewhat greater variability, the variations are seen to be about equal in both directions from the average, thus failing to substantiate the assumption that the palates of the feeble-minded are relatively narrow. Finally, all the differences in size discovered by Channing and Wissler are too small to be detected by the eye and are of no clinical value. The results suggest that the differences in variability shown for the feeble-minded are due to a general retardation effect during the first few years of life.

COMBINING CLINICAL AND LABORATORY WORK.

The opening of the new laboratory of experimental medicine and the inauguration of a new chair in that subject at Western Reserve University form a notable event in the development of medical research and education. For many years the dominant tendency of medicine has been toward specialization. The rapid advance, both of the fundamental medical sciences and of the practical arts of medicine and surgery, has to a great extent been rendered possible only by this ever-increasing specialization. But the time has come—and this fact is recognized by all—when this minute subdivision of knowledge and of effort, so admirably an instrument of progress up to a certain point, threatens to separate our science into a number of isolated fields, each known only to its own cultivators, and especially to hinder those fundamental studies, sometimes inappropriately called "theoretical," from those designated by a superficial antithesis the "practical" branches.

It is as vain to hope as it would be unwise to desire that the investigator, in the one field or in the other, should cease to specialize. He must specialize in order to discover new truth. The only antidote to excessive specialization is to provide the means of synthesis. It is the aim of such a laboratory as is here referred to to aid in this synthesis, to do something toward bridging the gap between laboratory and clinical work, primarily as regards investigation, but also in relation to the instruction of students. To better accomplish it—and this is a matter of peculiar interest and importance—a definite official contact with clinical material in one or more of the local hospitals is to be assured to the laboratory staff by the appointment of the director and possibly of other members of the staff to clinical positions. In this way it is hoped to provide for the exact clinical study of selected groups of cases, combined with experimental study not only of material obtained from the cases but also of the clinical phenomena so far as they can be reproduced or elucidated by simultaneous investigations on animals.

It is this definite association of the laboratory with the hospital which constitutes the special feature of this new foundation and defines its special field. The field of medical teaching will profit by the creation of more laboratories of this very sort. We now possess a not very small and a growing number of clinical laboratories of experimental pathology and institutes for medical research. The Cushing laboratory at Cleveland is not merely an addition to this important, and, indeed, indispensable group. It is not, for example, intended to be a miniature of the Rockefeller Institute at New York, for it is an integral part of a medical school and intimately related to the hospitals associated with that school. It will not usurp the functions of the clinical laboratory, for its special office will not be the examination, chemical, histologic or bacteriologic, of material for purposes of diagnosis. Nor will it encroach on the domain of the laboratory of experimental pathology, properly so-called, for it will not, in general, undertake the investigation of problems of diseased function as laboratory problems alone. It is the definite and system atic association of the experimental with the clinical work which constitutes the distinctive note of the new departure, and it is chiefly this which renders it so interesting and promising a venture.

[1] Channing, Walter, and Wissler, Clark: The Hard Palate in Normal and Feeble-Minded Individuals. Anthropological Papers of the American Museum of Natural History, I, part 3. Paper. Pp. 349, with illustrations. Price, $0.50. New York: Published by Order of Trustees.

THE DOCTRINE OF LYMPHATIC PERMEATION IN CANCEROUS METASTASES AND ITS SIGNIFICANCE FOR RADICAL OPERATIONS.

Few contributions to medical knowledge should meet with a more cordial reception than one increasing the brightness of the ultimate prognosis in operations for cancer of the breast. Such a contribution seems to exist in the researches of W. Sampson Handley[1] on the "modes of dissemination of breast cancer metastases."

The only hypothesis which has gained wide acceptance as an explanation for cancer metastases in the parietes and viscera is that which attributes the secondary growths to a transmission to distant parts of cancer emboli, which have reached the blood stream through the lymphatics or by direct invasion of a vein. But, if cancer metastases are the result of embolic dissemination, how do the lungs ever escape? Why are the liver and the skeletal system so frequently the seat of secondary growths, while the spleen is relatively immune? These and other equally poignant objections have long rendered the embolic hypothesis untenable for many observers; it appears to have survived merely in default of a more worthy successor.

Handley, from a careful clinical, macroscopic and microscopic study of cancer dissemination, concludes that, while blood embolism may occasionally be responsible for secondary growths, it is, comparatively speaking, a negligible factor, the real danger being a progressive permeation by cancer cells of the lymphatic vessels which lie just superjacent to the deep fascia. This vast lymphatic system, which may be termed the fascial lymphatic plexus, is coextensive with the body, receiving vertical tributaries from the skin and from the tissues subjacent to the deep fascia. In a convincing way Handley has shown that the permeation of this lymphatic meshwork by growing cancer cells is the true explanation of metastatic cancer. The growth of the cancer cells along the lymphatics is not alone in a horizontal direction, but they permeate upward through the skin tributaries, forming cutaneous nodules, and downward through the deep connections, producing visceral metastases.

It is impossible to speak here of the many interesting details of the author's work, but the immense practical bearing of his conclusions on the operation for breast cancer and on the ultimate prognosis is obvious. The surgical indications are clear. Since dissemination takes place along the deep fascial lymphatic plexus by a process of permeation, an operation for breast cancer should and does include not only a liberal removal of skin, but also a widespread removal of the adjacent deep fascia.

LETTER BROKERS AND THE CONFIDENCES OF THE GULLIBLE.

Our exposure of the Epileptic Institute Company of Cincinnati in The Journal, Nov. 28, 1908, called attention once more to the close relation between the letter brokerage business and advertising quacks. Kalmus, the promoter of the Epileptic Institute, made a practice, the report said, of "purchasing the names and addresses of epileptics from the Guild Company of New York." This is but another concrete instance of the fact that people who are foolish enough to confide in these advertising quacks are not only "squeezed" for all that can be got out of them, but that insult is added to injury. The confiding patient, sooner or later, realizes that he has been fleeced. Then, being commercially valueless to the quack who has robbed him, his name and address and the letters he has written are sold to agencies that make a business of reselling or renting out such good gullible material for kindred frauds to prey on. We have in our possession a list of letters for rent by this same Guild Company, containing communications on such subjects as syphilis, female complaints, drug habits, alcoholism, etc., addressed by sufferers to various advertising quacks. These letters assuredly were written under the belief, and doubtless often under the direct assurance, that the writer's private and personal confidences would be closely guarded. It can hardly be supposed that the misguided sufferers would have laid bare the most intimate of personal details had they supposed that their letters would be not only handled and read by sundry people, but let out on hire to any quack who will pay the price. Yet it is by this means that the gullible sick are bombarded with circulars regarding their illnesses, in which the advertisers "have become interested" through the tender solicitude of some mysterious "friend."

FOOTBALL CASUALTIES.

Reformed football, judging from the results of the late season, seems to be about as fruitful in serious accidents as it was before the change of rules, which, it was supposed, would render the game less objectionable in this respect. The reported cases of broken arms, legs, ribs, collar bones, etc., are more numerous than they were last season, and while it is too early yet to reckon the fatalities, since in many cases death is not immediate, the number is still a formidable one, considering the fact that at the most the number of participants in the game is comparatively small. One game is reported in which seventeen players had to be removed unconscious from the field, five of them injured so severely as to require hospital care. There is evidently need for more improvement.

Medical News

CONNECTICUT.

Society Meeting.—At the semi-annual meeting of New Haven County Medical Association, the followng officers were elected.: Dr. William J. De Laney, Naugatuck, president; Dr. Frank N. Loomis, Derby, vice-president; Dr. William S. Barnes, New Haven, clerk (re-elected); Dr. Charles S. Rodman, Waterbury, member of executive committee (re-elected); and Drs. Norton R. Hotchkiss, New Haven, Henry G. Anderson, Waterbury, and Edward W. Smith, Meriden, censors.

Against Contract System.—The Bridgeport Medical Society, at a meeting November 17, took action to prevent its members from making contracts with fraternal organizations to treat members on a per capita basis. A resolution was adopted whereby the by-laws were amended to take effect January 1, prohibiting any member of the society from holding a contract with any fraternal organization, and members of the association will be prohibited from consulting with contract physicians after that date.

ILLINOIS.

Psychopathic Hospital to be Recommended.—The citizens' committee, which recently investigated the Cook County Hospital for the Insane, Dunning, in its official report, recommends the establishment of a psychopathic hospital, where patients can be treated before being committed to the state hospitals.

Personal.—Dr. John C. Gunn, Bellville, has returned after six months abroad.——Dr. Charles F. Read, Genvea, has been appointed assistant physician in the Illinois Eastern Hospital for the Insane. Hospital.——Dr. William B. Peck, Freeport, who has been abroad for a year, is expected to return and resume practice early in January.

Chicago.

Personal.—The condition of Dr. Sarah Hackett Stevenson, who has been ill for a long while in St. Elizabeth's Hospital, is reported to be critical.——What is supposed to have been a bomb was thrown into the automobile of Dr. Merritt O. Hoover, an official of the health department, December 7. Dr. Hoover is said to have admitted that he had received several threatening letters prior to this occurrence.——Dr. Joseph Springer has been appointed coroner's physician, vice Dr. Otto W. Lewke, resigned.——Dr. Edmund J. Doering has returned from England.

Mortality of the Week.—During the week ended December 12, 537 deaths were reported to the Department of Health, 17 more than for the preceding week and 57 fewer than for the corresponding week of last year, the respective annual death rates per 1,000 being 12.92, 12.52, and 14.70. Pneumonia caused 79 deaths; heart diseases, 57; consumption, 53; violence (including suicide), 38; acute intestinal diseases, 33; cancer, 31, and nephritis, 30; while of the chief communicable diseases there were 23 deaths due to diphtheria; 14 to scarlet fever; 5 to measles, and 2 to typhoid fever. There was a marked reduction in the deaths from impure air diseases, which were 44 fewer than for the corresponding week of 1907.

Contagious Diseases.—The chief medical inspector gives a brief summary of the contagious disease situation for the week ended December 12. During the week 867 cases were reported to the department, distributed as follows: Diphtheria, 222; scarlet fever, 213; chickenpox, 132; measles, 98; tuberculosis, 82; typhoid fever, 47; pneumonia, 26; whooping cough, 21; and diseases of minor importance, 26. Compared with the preceding week there were 30 more cases each of diphtheria and scarlet fever, 39 more of chickenpox, and 12 more of whooping cough. During the week the medical inspectors excluded 442 out of 12,227 pupils examined on account of contagious diseases. The principal causes of exclusion were: Diphtheria, 5: contacts, 23; scarlet fever, 11; contacts, 11; measles, 7: contacts, 14: chickenpox, 52; contacts, 19; whooping cough, 1: contacts, 2: mumps, 12; contacts, 3; tuberculosis, 3; tonsillitis, 104; pediculosis, 46; favus, 2; scabies, 15; impetigocontagiosa, 60; ring worm, 17, and conjunctivitis, 8.

INDIANA.

Personal.—Dr. Edgar C. Loehr, Noblesville, has been reappointed secretary of the Hamilton County Board of Health.——Dr. Francis M. Ihrig, Goshen, has been re-elected secretary of the Board of Health of Elkhart County.——Dr. Frederick W. Shaley, Terre Haute, has succeeded Dr. Maurice B. Van Cleave as secretary of the Vigo County Board of Health.——Dr. Henry W. Held, Vincennes, who has been seriously ill, is reported to be imporving.——Dr. J. Willard Parrish, Shelbyville, is reported to be seriously ill with appendicitis.——Dr. Lorin W. Smith, Wabash, who was recently operated on for septicemia, is reported convalescent.——Dr. George T. MacCoy, Columbus, has been appointed a member of the State Board of Health.——Dr. William O. Gross has been elected secretary of the Hope Hospital Association, Fort Wayne.——Dr. Leopold Heimann, Evansville, has returned from Europe.

IOWA.

Sanatorium Cornerstone Laid.—The cornerstone of the new state sanatorium at Nevada, was laid November 11, with impressive ceremonies.

Itinerants Refused License.—At the October meeting of the State Board of Medical Examiners, itinerant practitioners' licenses were refused to Drs. Wilbur, W. E. and J. F. Shallenberger. The board announces that there are in Iowa only two itinerant practitioners, Drs. B. A. Stockdale and A. H. Weber.

Personal.—Dr. Charles J. Plonske, Bancroft, has returned after a year abroad.——Dr. William E. Sanders, Alta, has returned after two years abroad and has accepted a voluntary assistantship in Johns Hopkins Medical School, Baltimore.——Dr. Rosa M. Upson Liebig, Marshalltown, has been appointed overseer of the poor.——Dr. Alexander W. Trout, Perry, was struck by a locomotive recently, and seriously injured.

KENTUCKY.

Correction.—In The Journal of September 12, was printed a death notice of Dr. Manuel H. Davis, Mays Lick. This notice was incorrect, as Dr. Davis is reported to be alive and in good health, and in active practice. The information on which the notice was based was the September, 1907, number of the *Louisville Medical Journal*, which noted the death of "Dr. M. A. Davis of Mayslick," but evidently referred to the late Dr. James D. Davis of Maysville.

Epidemic Diseases.—The secretary of the State Board of Health announces that smallpox has existed in Hopkins county for several weeks. There is no isolation hospital in the county and the disease has spread until it is reported that there are about 25 cases in Madisonville and others in many of the mining towns in the county. Negroes are chiefly afflicted. A contract has been awarded for the erection of an isolation hospital near Madisonville for white patients, and another will be built and used for colored patients.——Typhoid fever is reported to be epidemic in Georgetown, and on this account Georgetown College has been closed until January 5.

MASSACHUSETTS.

Osteopath Convicted.—John A. Taff, an osteopath of Boston, formerly of Louisville, Ky., charged with practicing medicine without being registered as a physician, is said to have been sentenced to imprisonment for three months in the House of Correction.

Medical Club Election.—At the annual meeting of the Brookfield Medical Club, held in West Brookfield, November 18, the following officers were elected: President, Dr. Albert F. Peck, Spencer; vice-president, Dr. Lawrence T. Newhall, Brookfield; secretary-treasurer, Dr. William J. Heffner, Gilbertville, and executive committee, Drs. Maurice W. Pearson, Ware, Charles A. Blake, West Brookfield, and Albert H. Prouty, North Brookfield.

Against Tuberculosis.—The Northampton Tuberculosis Association, at its annual meeting, elected Dr. Albert M. Belden president.——At the meeting of the Antituberculosis Association, held recently in Quincy, the following officers were elected: President, Dr. John F. Welch; vice-presidents, Drs. Henry C. Hallowell and John A. Gordon; secretary, Dr. Walter L. Sargent; members of the board of managers, Drs. Nathaniel S. Hunting, Willis J. Middleton, Daniel B. Reardon, John T. Reynolds and Elmore R. Johnson.

Free Medical Lectures.—Beginning January 3, there will be given at the Harvard Medical School, on Saturdays at 8 p. m., and on Sundays at 4 p. m., the second annual series of thirty-two free public lectures. The dates, subjects and speakers are as follows:

Jan. 3.—"Fifty Years of Surgery: A Review," by Dr. David W. Cheever, '52.

Jan. 9.—"Some Things Parents Should Know About the Teeth of Their Children," by Dr. Charles A. Brackett, '73.

Jan. 10.—"Anatomical Variations," by Dr. Thomas Dwight, '66.

Jan. 16.—"Auditory Vertigo: Deafness Due to Ear Disease," by Dr. Clarence J. Blake, '65.

Jan. 17.—"Inflammation," by Dr. William T. Councilman, hon., '99.

Jan. 23.—"Diphtheria and Scarlet Fever," by Dr. John H. McCollom, '69.

Jan. 24.—"The Circulation of the Blood," by Dr. William T. Porter.

Jan. 30.—"On the Work for the Relief of the Sick of Various Agencies Other Than Medical," by James J. Putnam, '66.

Jan. 31.—"Rabies (Illustrated)," by Dr. Langdon Frothingham, '89.

Feb. 6.—"Curvature of the Spine, and School Life," by Dr. Edward H. Bradford, '69.

Feb. 7.—"Methods of Testing the Acuteness of Vision and Color Perception," by Dr. Charles H. Williams, '71.

Feb. 13.—"Psychotherapy; Its Use and Abuse." by Richard C. Cabot, '89.

Feb. 14.—"Infantile Paralysis and Its Treatment," by Dr. Edward H. Bradford, '69.

Feb. 20.—"The Teeth of Public School Children; How Related to the Children's General Health and Development," by Dr. William H. Porter, '78.

Feb. 21.—"Psychotherapy; Its Use and Abuse (II.)," by Dr. Richard C. Cabot, '89.

Feb. 27.—"A Study of the Inoculable Tumors of Mice, with Special Reference to Heredity (Illustrated)," by Dr. Ernest E. Tyzzer, '02.

Feb. 28.—"The Hygiene of Pregnancy (to women only)," by Dr. Charles M. Green, '74.

March 6.—"Glucose," by Dr. Lawrence J. Henderson, '98.

March 7.—"Pneumonia," by Dr. Elliott P. Joslin, '95.

March 13.—"Feeding and Its Relation to the Infant's Development," by Dr. John L. Morse, '87.

March 14.—"School Life and Its Relation to the Child's Development," by Dr. Thomas M. Rotch, '01.

March 20.—"Some Facts as to Disease of the Heart," by Dr. Henry Jackson, '80.

March 21.—"The Relation of Gastroenteric Conditions to the Development of Early Life," by Dr. Charles H. Dunn, '96.

March 27.—"Dental Hygiene in the School and Home," by Dr. Samuel A. Hopkins.

March 28.—"State Work in Tuberculosis," by Dr. Arthur Tracy Cabot, '72.

April 3.—"The Work of the Boston Consumptives' Hospital," by Dr. Edwin A. Locke, '01.

April 4.—"Psychotherapeutics," by Dr. Philip C. Knapp, '78.

April 10.—"The Diagnosis and Prognosis of Surgical Affections, with Special Reference to Their Early Detection and Treatment," by Dr. Maurice H. Richardson, '73.

April 11.—"Progress in the Treatment of Cancer," by Dr. James G. Mumford, '85.

April 17.—"Good and Evil Results of Athletics," by Dr. Edward H. Nichols, '86.

April 18.—"The Artificial Illumination of Schoolrooms," by Dr. Myles Standish, '79.

April 24.—"Athletic Sports at Various Ages and Their Probable Results on the Body," by Dr. J. Bapst Blake, '87.

April 25.—"Louis Pasteur," by Dr. Harold C. Ernst, '76.

NEBRASKA.

New Infirmary.—The Franciscan Brotherhood of Poor St. Clares is erecting an infirmary at Twenty-ninth and Hamilton streets, Omaha, at a cost of $31.000.

Society Election.—The Highline Medical Society of Phelps county has elected Dr. William A. Schreck, Bertrand, president; Dr. G. E. Charton, Moorefield, vice-president; and Dr. Alfred E. Reeves, Farnam, secretary-treasurer.

Personal.—Dr. Frederick J. Wearne, Omaha, has gone to Europe.——Dr. Archibald G. Fletcher, Orchard, has decided to enter the missionary field and expects to go in a short time to Corea or China.——Dr. H. H. Blodgett has been made assistant to Dr. Emanuel S. Wenger in the Burlington medical department, Lincoln.

NEVADA.

State Society Election.—At the annual meeting of the Nevada State Medical Associaton, held in Reno, November 10 and 11, the following officers were elected: President, Dr. John A. Lewis, Reno; vice-presidents, Drs. George F. Pope, Battle Mountain, and Walter W. Ryan, Goldfield; and secretary-treasurer, Dr. Sidney K. Morrison, Reno. Resolutions were drafted and sent to the Nevada senators and congressmen, appealing to them to do all in their power to support the policy of President Roosevelt regarding a national health bureau, and calling their attention to the Committee of One Hundred, which, through its chairman, Dr. J. N. McCormack, will bring this before Congress in the near future.

NEW YORK.

Presentation to Dr. Park.—Students of the senior class of the Medical Department of the University of Buffalo, presented Dr. Roswell Park with a silver service in honor of his completion of a quarter of a century as professor of surgery in the institution.

Optometry Rules Approved.—Rules governing the practice of optometry were approved on December 10 at a meeting of the regents of the university, Albany. The regulations affecting the examination of applicants are along the lines of those prescribed by the recently enacted law. It was provided that the minimum time in registered schools should, after a reasonable time, be two years. Students in any of the schools now in existence will be eligible to try the tests next January.

Personal.—Dr. Renwick R. Ross, superintendent of the Buffalo General Hospital, has declined the superintendency of Bellevue Hospital.——Dr. Russell B. Lynn, Waverly, has sailed for Vienna.——Dr. Charles G. Child, Jr., New York City, has been appointed visiting gynecologist to the City Hospital.——Dr. Hiram B. Manchester has been elected town physician of Batavia.——Dr. Earl G. Danser, Buffalo, has been appointed medical examiner, and Dr. John D. Howland, Buffalo, assistant medical examiner of Erie county.——Dr. Herbert W. Williams, Buffalo, sustained painful injuries in an automobile accident recently.

Vital Statistics.—The returns of deaths for October show a slight decrease as compared with last year. There were reported 10,880 deaths, equivalent to an annual death rate of 15.3 per 1,000, while the rate for October, 1907, was 16.6 per 1,000. There were 169 deaths from typhoid fever, 55 more than for October, 1907, and 32 fewer than for a five year's average for the month. Deaths from measles and diphtheria decreased from 34 and 195 to 13 and 172 respectively. Pulmonary tuberculosis caused 4 more deaths than in October, 1907, and 6 more than the average for five years. Malignant disease shows an increase of 61, as compared with last year. Diseases of the nervous system caused 896 deaths, or 287 fewer than for last year. There were 148 deaths from suicide, 15 from homicide, and 424 from accidents.

State Sanitary Officers in Convention.—The eighth annual conference of the sanitary officers of the state was held in Albany on December 1, 2 and 3. At the opening session Dr. A. H. Garvin of the New York State Hospital for the Treatment of Incipient Pulmonary Tuberculosis at Raybrook gave a clinical demonstration of the various measures employed in the diagnosis of incipient tuberculosis. Dr. Alec H. Seymour, secretary to the State Department of Health explained the new law relating to the registration of tuberculosis cases and Dr. Eugene H. Porter told of the results of the work of the state department and the plans that were under way for relieving water pollution in the future. On the second day, Governor Hughes received the delegates to this convention and made an address. The problems of pure water and pure milk were discussed. A few interesting facts were brought out in regard to vital statistics. New York State has a higher death rate than Maryland, Colorado, Maine, Connecticut, New Jersey, Vermont, New Hampshire, Pennsylvania or Massachusetts, but a lower death-rate than Rhode Island and perhaps California. The death rate of New York City has decreased steadily and rapidly since 1872, but is still higher than that of London, Paris or Berlin. The birth rate of New York State, if statistics are correct, is lower than that of any other state except Michigan.

New York City.

Gift for Hospital.—The Hospital for Deformities and Joint Diseases has just received $5,000 as the net proceeds of a bazaar.

Parks Should Have Dairies.—The agitation for dairies in the various city parks has resulted in raising by subscription over $1,500 for this purpose.

Harvey Society Lecture.—The sixth lecture on the Harvey Society course, delivered by Prof. A. B. Macallum of the University of Toronto, on December 19, at the Academy of Medicine, is on the subject of "Osmosis."

The Tuberculosis Exhibit.—Because of the full attendance at this exhibit, the Sunday closing hour will be 10 p. m. instead of 1 o'clock as in the past. On December 6 thousands were turned away after the closing at 5 p. m.

Health Lectures.—The Board of Education is presenting a course of health lectures at the different public schools. These lectures treat of subjects such as the care of the teeth and skin, and suggestions in regard to the prevention of tuberculosis.

Needs Appropriation.—Dr. Darlington has asked the Board of Estimates and Apportionment for an appropriation of $52,000 to pay 100 physicians and 200 nurses employed by the Department of Health in the bureau of school hygiene for the medical inspection of school children.

Tuberculosis Wards Few.—There is a general lack of accommodations for tuberculosis patients in all the city hospitals. The contract for a second building for the new tuberculosis infirmary, which is an addition to the Metropolitan Hospital on Blackwell's Island, has been left. According to the estimates the new building will cost about $200,000, and will have a capacity of 224 beds.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 5, 574 cases of tuberculosis, with 153 deaths; 385 cases of diphtheria, with 39 deaths; 271 cases of measles, with 10 deaths; 221 cases of scarlet fever, with 7 deaths; 77 cases of typhoid fever, with 11 deaths; 37 cases of whooping cough, with 1 death; 5 cases of cerebrospinal meningitis, with 1 death; and 179 cases of varicella, a total of 1,749 cases and 222 deaths.

The Opening of the Tuberculosis Exhibit.—The tuberculosis exhibit was opened November 30 by Mayor McClellan and addresses were made by Health Commissioner Darlington, Robert W. de Forest, president of the Charity Organization Society; Henry F. Osborn, president of the Museum of Natural History; Dr. Abraham Jacobi, and others. The mayor announced that there were at present about 3,500 beds available for tuberculosis patients in the public and private institutions of the city, and buildings were in the course of construction, or have been planned, which will accommodate nearly 1,500 more. Eventually the present plans provide for 6,000 patients. The large crowds attending the exhibition bear witness to the fact that the public is deeply interested. There are a series of meetings especially for physicians, among them a mass meeting of physicians, which was held on Friday evening, December 4, at which Dr. Herman M. Biggs presided. Dr. Darlington has announced that since the department of health has begun its campaign against spitting and has removed advanced cases of tuberculosis to hospitals, furnished sputum cups, and enforced disinfection of rooms vacated by persons suffering from consumption, the death rate from that disease among children under 15 years of age has fallen from 7.1 for each 10,000 of population to 2.6.

NORTH CAROLINA.

Personal.—Dr. Edward R. Michaux, Greensboro, has resigned as medical director of the Security Life and Annuity Company, and will resume private practice. Dr. J. Pinkney Turner, assistant medical director, has succeeded him.——Dr. Ephraim M. Brevard, for several years in practice in Tallahassee, Fla., will return to Charlotte, January 1, and resume practice.

Society Meeting.—At the annual meeting of Mecklenburg County Medical Society, held in Charlotte December 1, the following officers were elected: President, Dr. Annie Laurie Alexander; vice-presidents, Drs. Robert Lafferty and Simril M. Henderson, and secretary, Dr. Leone B. Newell, all of Charlotte.——The Highpoint Academy of Medicine, at its annual meeting December 2, elected Dr. John T. Burrus, president; Dr. Claude E. Reitzel, vice-president, and Dr. G. F. Duncan, secretary-treasurer.

OHIO.

New Building for University.—Cincinnati University is to have a new building for the College of Medical Sciences to cost $275,000, besides $25,000 for equipment.

Cincinnati.

Fight for Pure Milk.—A new step in the fight for pure milk was taken when the Board of Health ordered the dairy stable of Henry Sielkop to be vacated. It is said that a number of other insanitary stables are to receive similar treatment. The milk commission has put under bonds of $500 each five producers and dealers not to sell milk from cows fed on distillery waste. Ten other producers and dealers were each fined $50 and costs.

"Patent Medicine" Prescribers.—At the annual meeting of the Ohio Druggist's Association, held November 24, war was declared on those physicians who prescribe "patent medicines." The druggists declared that the percentage of prescriptions of this nature has become so large that should it continue it would be only a matter of a short time until druggists would be reduced to the position of clerks who "buy large bottles from manufacturers and fill small bottles for the doctors." Edward Noes, Jr., received the unanimous endorsement of the association for membership on the State Board of Pharmacy.

Miami Alumni Election.—At the regular monthly meeting of the Cincinnati chapter of the Miami Medical College Alumnal Association, held November 27, the following officers were elected: President, Dr. John A. Caldwell; secretary, Dr. J. Edward Pierring; and treasurer, Dr. William C. Herman.

PENNSYLVANIA.

Philadelphia.

Tuberculosis Exhibition.—Plans have been completed for the Tuberculosis Exhibition to be held in this city for one month, beginning February 1 and continuing one month The exhibition will be composed largely of the material exhibited at the recent International Tuberculosis Congress in Washington. Among the individual exhibits are eight which received from the Congress prizes ranging in value from $100 to $1,000. Besides these, 44 of the exhibits received gold medals, and 43 silver medals. The exhibit is unique, not only in the fact that it is the greatest of its kind ever gathered together, but also because this demonstration, collected for a purely educational purpose, is used to illustrate the dangers of only one disease.

Health Report.—The total number of deaths reported to the Bureau of Health for the week ended December 12, was 469. This is a decrease of 55 from the previous week and of 99 from the corresponding week of last year. The principal causes of death were: Typhoid fever, 12; diphtheria, 10; consumption, 53; cancer, 29; diabetes, 4; apoplexy, 18; paralysis, 5; heart disease, 47; acute respiratory diseases, 60; enteritis, 25; hepatic cirrhosis, 6; appendicitis, 5; acute nephritis, 7; Bright's disease, 38; premature birth, 11; congenital debility, 8; senility, 5; suicide, 6; accidents, 25; and marasmus, 3. There were 199 cases of contagious diseases reported, with 26 deaths, as compared with 197 cases and 24 deaths reported in the preceding week.

Foes of Nostrums Meet.—Four hundred and fifty druggists and physicians attended a banquet and "getting together meeting" at the Columbia Club, December 9, for the purpose of discouraging the use of nostrums by the public and the prescribing of these agents by the physicians. The meeting was addressed by Dr. Albert M. Eaton, president of the county medical society, and Drs. G. Morton Illman, A. B. Hirsch, Frederick A. Sutliff. Dr. Eaton claimed that the public school should be made available for the education of the public against the use of dangerous proprietary medicines. He said that pharmacists and physicians should be allowed to visit the schools and deliver short plain talks on the dangers of nostrum dosing. He also advocated the introduction of lectures against the prescribing of nostrums into the study course of the senior classes of medical colleges.

Medical Society's Attitude Defined.—At a recent meeting of the Philadelphia County Medical Society, the following resolution, concerning the action of the outside schools, was adopted:

> "WHEREAS, willful misstatements by certain interested elements in the community throw an incorrect light on the attitude of *and are evidently intended to interfere with the regular medical* profession in its efforts to protect the public by suppressing medical criminals and illiterates, be it
>
> "*Resolved*, That the Philadelphia County Medical Society, as the exponent of the recognized profession in this teaching center, declares its belief in the right of a physician to use mental, chemical, mechanical, electrical, manipulative, dietetic or any other legitimate means of treating disease; the same holds true of dosage, small or large. Furthermore, the society embodies the modern spirit as to professional fellowship, and points with pride to its record for broad-minded liberality in election to its membership. Graduates of various 'schools' of practice have been and are now *on its rolls*."

SOUTH CAROLINA.

Medical Scholarships.—The governor of the state has awarded scholarships in the Medical College of the State of South Carolina as follows: W. U. O'Bryan, Manning; J. H. Cannon, Ridgeland: E. E. Epting, Williamston; John M. Beardon, Enoree; Phillip W. Hunter, Yorkville; Floyd D. Rogers, Lake City; and George H. Hennies, Columbia.

Society Meetings.—At the annual meeting of Lexington County Medical Society, held in Lexington, October 5, Dr. William L. Kneece, Baxter, was elected president; Dr. Rufus E. Mathias, Irmo, vice-president, and Dr. James J. Wingard, Lexington, secretary (re-elected).——The annual meeting of Laurens County Medical Association was held in Laurens November 26, when the following officers were elected: Dr. Samuel F. Blakely, Ora, president; Dr. Dorroh H. Ferguson, Laurens, vice-president; Dr. Jesse H. Teague, Laurens, secretary; Dr. Absalom J. Christopher, Laurens, treasurer, and Drs. Samuel F. Blakely, Ora, and William H. Dial, Laurens, delegates to the state association.

SOUTH DAKOTA.

Typhoid Epidemic.—Reports from Clear Lake tell of an alarming epidemic of typhoid fever, for which no cause has as yet been determined.

Election.—At the annual meeting of the Black Hills Medical Association, held in Deadwood, November 15, the following officers were elected: President, Dr. Alfred G. Allen, Deadwood; vice-president, Dr. Adolph M. Giffin, Rapid City; secretary, Dr. Felix E. Ashcroft, Deadwood; treasurer, Dr. Walter L. Vercoe, Lead, and censors, Drs. C. W. Hargens, Hot Springs, and John W. Freeman, Lead.

TENNESSEE.

Dispensary in Police Station.—Under direction of Dr. James L. Andrews, president of the board of health of Memphis, a room in the police station is to be fitted up as a dispensary, where emergency and charity cases may be treated.

Fight Tuberculosis with Phonograph.—The board of health of Memphis has arranged a brief series of lectures on "Tuberculosis," laying stress on the way of avoiding the disease, what to do if the disease is contracted, and making special mention of the spitting habit. These lectures are to be communicated to the people by means of a phonograph placed at the corner of Main Street and Madison Avenue.

Society Meetings.—At the annual meeting of Greene County Medical Society, held November 2, the following officers were elected: President, Dr. Isaac B. Brown, Mosheim; vice-president, Dr. Martin A. Blanton, Baileyton, and secretary-treasurer, Dr. S. Walter Woodyard, Greenville.——At the twenty-seventh semi-annual session of the Middle Tennessee Medical Association, held in Clarksville, November 19 and 20, the following officers were elected: President, Dr. Leonard E. Ragsdale, Williamsport; vice-president, Dr. Benjamin F. Fyke, Springfield, and secretary-treasurer, Dr. R. Logan Jones, Nashville.

VERMONT.

College Opens.—The fifty-fifth annual session of the University of Vermont, College of Medicine, Burlington, commenced *November 7. The principal speaker was Dr. J. W. Seane, professor* of physiology in the university.

Personal.—Dr. D. M. Shea, Burlington, sailed for Europe *October 29.——Dr. Bingham H. Stone has been reappointed* director of the laboratory of the State Board of Health, Burlington, and C. P. Moat, L. P. Sprague, and Hugh Thompson have been chosen assistants.

Infectious Diseases.—On November 16, more than forty cases of smallpox were reported in Brattleboro and half a dozen smaller towns in southeastern Vermont. The diagnosis of the State Board of Health and the Brattleboro Board of Health was confirmed by the chief diagnostician of the health department of New York City. Five new cases of smallpox *were reported November 21. The secretary of the State Board* of Health reports that the severe cases are improving and that there is practically no danger of the spread of the infection. On November 28, there were seventeen houses under quarantine in Brattleboro with twenty-two patients and five patients at the Isolation Hospital.——Typhoid fever is said to be very prevalent at St. Albans, where nearly fifty cases are under treatment.

WASHINGTON.

Society Meeting.—At the bi-monthly meeting of Whitman County Medical Society, *held in Tekoa, November 16, the need* was urged of better laws relative to mental examination of the criminal insane. A committee consisting of Drs. William B. Palamountain, Colfax, Robert J. Skaife, Colfax, and Cardwell, was appointed to confer with the senators and representatives and arrange for the passage of such a law. Dr. William B. Palamountain was elected president; Dr. A. J. Nelson, vice-president, and Dr. J. Earle Else, Palouse, secretary-treasurer.

WISCONSIN.

Personal.—Dr. *William A. Henke, Tomah, has returned from* Europe.——Dr. Leonard E. Spencer, Wausau, a member of the State Board of Health, has retired from practice and has disposed of his practice to Dr. J. R. Bryant.

Antituberculosis Association Formed.—The Wisconsin Antituberculosis Association has been organized at Milwaukee, with 800 charter members, and with the declared object of carrying on the fight against tuberculosis. Dr. Mazyck P. Ravenel, Madison, has been elected president, and Dr. D. C. Baer, Milwaukee, secretary.

Society Meeting.—At the annual meeting of Crawford County Medical Society, held in Wauzeka, November 24, Dr. Frank J. Antoine, Prairie du Chien, was elected president; Dr. B. F. Taylor, Mount Sterling, vice-president, and Dr. George H. Perrin, Wauzeka, secretary-treasurer.

Sanatorium Overcrowded.—The State Tuberculosis Sanatorium, Wales, in which there is accommodation for 60 patients, now has a population of 189, and the board of control has decided to ask permission to borrow $2,000 from the general fund and has asked the legislature for an appropriation for additional buildings.

GENERAL NEWS AND COMMENTS.

New General Hospital.—A general hospital is being constructed in Pueblo, Mexico, to cost about $80,000, and to accommodate about 600 patients. It is expected that the institution will be ready to open in the fall of 1909.

Physician Wanted for Hospital for Insane.—The United *States Civil Service Commission* announces an examination on Jan. 13, 1909, at the regular locations throughout the United States, for a medical interne (female) in the Government Hospital for the Insane, Washington, at $600 a year, with maintenance. Each applicant must be unmarried, a citizen of the United States (or about to become such), a graduate of a reputable medical college within two years, and not under 20 years of age. The applicant may apply to the commission at Washington, or to the secretary of any board of examiners. Request should be made for application blank 1312. The commission has experienced difficulty in filling this vacancy, and therefore calls particular attention to this examination.

Society Meetings.—At the annual meeting of the New England Pediatric Society, November 28, papers were read on "Psychotherapy as Applied to Children," by Dr. Alexander C. Eastman, Springfield, Mass.; on "Aplastic Anemia," by Dr. Ralph C. Larrabee, Boston, and Dr. Timothy Leary, Boston; on "Fibroid Phthisis in Childhood," by Dr. Arthur W. Fairbanks, Boston; and on "Human Milk in the Treatment of Various Infections," by Dr. Francis P. Denny, Brookline, Mass. Dr. Charles W. Townsend, Boston, was chosen president; Dr. Addison S. Thayer, Portland, Maine, vice-president; Dr. Fritz B. Talbot, Brookline, Mass., secretary and treasurer, and Dr. Arthur H. Wentworth, Boston, member of the council.——The annual meeting and dinner of the Interurban Academy of Medicine was held in Superior, *Wis., November 18. Dr. John* M. Robinson, Duluth, was elected president; Dr. H. Jefferson O'Brien, Superior, vice-president; Dr. C. T. Haney, Duluth, secretary-treasurer, and Dr. George H. Conklin, Superior, censor.——At the twenty-fifth annual convention of the Tri-State Medical Association of Arkansas, Mississippi and Tennessee, held in Memphis, November 24, 25 and 26, the following officers were elected: President, Dr. William H. Deaderick, Marianna, Ark.; vice-presidents, Drs. T. S. Hare, Vincent, for Arkansas, S. Wade Glass, Dublin, for Mississippi, and James A. Porter, Ripley, for Tennessee; secretary, Dr. J. H. Eugene Rosamond, Memphis, and treasurer, Dr. J. A. Vaughn, Memphis.

FOREIGN.

The Nobel Prizes.—News by cable confirms the statement in The Journal last week, page 2069, that the Nobel prize for medicine was to be divided this year between P. Ehrlich of Frankfurt a. M. and E. Metchnikoff of the Pasteur Institute, Paris, the leading immunologists of the world. Ehrlich was the guest of the University of Chicago in 1904, when an honorary degree was conferred on him. He also was presented in 1906, at the International Medical Congress at Lisbon, with the surplus left from the Paris International Medical Congress, which was awarded as a prize for his side-chain theory and work based thereon. Ehrlich was born in a small German town in 1854, and was Koch's assistant at Berlin until he became director of an institute for serum research and experimental therapy in 1896. Metchnikoff is a Russian, and, after studying in Germany, was professor of zoology and anatomy at Odessa until 1882, when he settled at Messina, where he published his works on phagocytosis. In 1886 he returned to Odessa as director of the bacteriologic institute, but preferring research to practical work, he offered his services to Pasteur, who placed a laboratory at his disposal, and here he has remained, notwithstanding brilliant offers from Russia and America. Metchnikoff never took a degree in medicine, but his theoretical, abstract work has supplied a solid basis for concrete medical achievements. The recipients of the Nobel prize for medicine have been: 1901, Behring; 1902, Ross; 1903, Finsen; 1904, Pawlow; 1905, R. Koch; 1906, Golgi and Cajal; 1907, Laveran, discoverer of the malaria parasite. Germany, Great Britain, Denmark, Russia, Italy, Spain and France have thus been honored, and this year the prize is divided between Germany and France. The only prizes that have come to America were the peace prize in 1906, given to President Roosevelt, and the physics prize last year awarded to A. Michelson, professor of the *Chicago University*. The chemistry prize this year was given to E. Rutherford of Manchester, England, who until within a year or so was professor *of physics at McGill College at Montreal.*

The Annual Burlesque Number of the Munich Medical Weekly.—The ninth comic number of the *Münchener medizinische Wochenschrift* has just been issued in honor of the seventy-fifth anniversary of the Munich medical union. It is sparkling with skits on all the latest medical achievements and topics. Not the least comical feature is that the journal is printed with the same departments, type and general make-up so that a second glance is necessary to detect the preposterous transformation in every department and advertisement. A new surgical instrument is described for which high claims are made, even to the extent of its inducing local anesthesia. It is called the tintinnabulotome, and consists of a scalpel with a baby's rattle on the outer end. The knife is concealed in the hand, and the child is pleased with the sound of the rattle. As it is a physiologic law that two sensations can not be perceived at the same time, the sensation of pain from the incision is overcome by the pleasurable auditory stimulus. In the "Current Literature Department," the *Grenzgebiete der Utopie und Ironie* is reviewed, with an abstract of an article which describes an improvement in the technic of lightning treatment of cancer, the author having succeeded in greasing the lightning. One review refers to "Rapid Medical Abstracts," indispensable for any physician who attempts to make summaries of medical articles. The author advises leaving the pages of the original uncut, as abstracts no longer attempt to give the ideas of the original author. The up-to-date abstract presents the views of the abstractor only. Editorial comment on this new book deplores the bad taste of those journals which have not yet outgrown the old practice of redigesting what the author has already digested. An original article describes the advantages of "Side Chains in Infant Feeding.". The writer listened to a lecture on "Side Chains," but could not make much out of it. He then asked a pharmacist if he kept side chains in stock, and the pharmacist supplied him with a "side chain powder," which he has been using with fine results in infant feeding. He confesses that he does not know what is in the powder, but he does not believe that those who give Mellin or Nestle or the like, know always what is in them. The results speak for themselves. A warm testimonial on a new preparation to promote the secretion of milk states that 17 of the 20 newly married women, to whom "Milchagol" was given, found their breasts increasing in size in a few months and were able to nurse their new-born children from one to forty weeks. It is mentioned that testimonials from the same author on 27 other new medicinal preparations are soon to be published. In "Correspondence" an inquirer wrote to know how long he should continue to treat heart disease with high power electric baths. The reply was given, "As long as the patient can stand it," and the inquirer writes again to know whether this refers to the physical or financial condition. The advertisement of the meat juice, Pureau, states that each jar represents a condensed ox, and that the juice is a most remarkable tonic for all who sell it, wholesale or retail. The advertisements for assistants state as the one requirement "ability to keep an automobile in repair." An internist who has hitherto had only chemical and histologic experience, but is a good hand with rabbits and dogs, advertises that he would like to get a little bedside experience during his free evening hours, to fit him for a professorship in internal medicine. A "Letter from America" denounces the German medical schools as not providing sufficient material for the students in proportion to their number. No student can learn how to manage a childbirth when there are only 900 in the year to 1,400 students. The writer during his course at a German medical school had opportunity to "conduct" a childbirth once in his entire course of obstetrics, and there were 18 other students and assistants present. He was able to catch a glimpse of the woman's arm and he heard the child cry—that was the extent of his connection with the case. In America, the writer continues, things are much better managed, there being plenty of medical colleges and plenty of childbirths so that there is no overcrowding. At the lying-in hospital connected with Honduras College, for instance, there are 3,000 childbirths annually and only 30 students following the course—the other 150 matriculated medical students are all away playing football or else are in the hospital being patched up after football. The writer ridicules the idea of teaching obstetrics from manikins, and says that it is much better to have 30 students to teach instead of 600 who crowd the amphitheater, but never come into personal contact with the teacher and can scarcely hear him, much less see him, on account of the crowding; who never get a chance to manage a childbirth or treat after-hemorrhage during their entire course, and yet are liable to penalty if they are guilty of any malpractice later. The comments on this delightful burlesque that have been made in previous years in The Journal apply to this latest number as well, and the "Berlin Letter" in these columns during the last few months gives the clue to some of the satires.

LONDON LETTER.

(From Our Regular Correspondent.)

London, Dec. 5, 1908.

Exhibition of Classified Drawings at the Polyclinic.

Sir Jonathan Hutchinson's exhibitions of classified drawings in his Clinical Museum at the Polyclinic are attended by large and interested audiences. The present exhibition deals with syphilis and is the largest yet made, over 500 drawings being displayed. On Wednesdays at 3 p. m. Sir Jonathan gives demonstrations in which he turns his collection to considerable account. The most important statement which it illustrates is that the term "soft chancre" has no definite meaning. A large collection of drawings of sores so termed by various writers is shown. The sores vary much in character and conform to no type. Sir Jonathan would abolish the term "soft chancre" entirely. All that can be said about a sore which does not show the characteristic induration of the true chancre is that it is not indurated, but the absence of induration is no guarantee whatever that the phenomena of syphilis will not supervene. In close connection with this group is a very important one termed by Sir Jonathan "herpetic chancres." It illustrates multiple sore in the coronal furrow arranged like a group of herpetic vesicles. Sir Jonathan suggests that sores which, owing to their multiplicity, have hitherto been regarded as typically "soft," are those of herpes which have been inoculated by venereal discharges, and of which one or more may assume induration at any time. Thus, multiplicity is by no means always a proof of autoinoculation and the term "herpetic chancres" becomes applicable. Portraits of unilateral groups of white patches in the mouth and throat described as "mucous patches" are also shown. Sir Jonathan also suggests that these are examples of herpes. The curious condition known on the European continent as "syphilitic leucoderma" on the back of the neck and shoulders is shown in several portraits. It does not appear to have ever been observed in England. Sir Jonathan Hutchinson suspects that the dappled appearance produced is caused by a deepening of tint rather than by bleaching and thinks that Fournier's appellation, "pigmentary syphilis," is the best.

The National Hospital for the Paralyzed and Epileptic.

This famous hospital, which may be described as the home of British neurology, since almost all the great neurologists of this country are connected with it, is again in need of enlargement. In half a century it has developed from a small house in Queen Square, Bloomsbury, in which the work was started, into a large hospital with 160 beds and 4,000 outpatient attendances annually, and a convalescent home in East Finchley standing in extensive grounds. A notable feature of the wards is the connection of each with a large and comfortably furnished day-room which is a boon to those patients not confined to bed. An increasing strain has been thrown on the electric department, where there are over 11,000 attendances annually. The accommodation is now limited to two small rooms. In consequence of the space required for the more modern *x*-ray and other apparatus, and the number of patients now attending, this department has had to be enlarged. There is an excellent up-to-date operating theater where Horsley's operations, so well known throughout the world, are performed. Last year fifty operations were performed on the brain and twenty-three on the spinal cord. To meet the heavy demands an extensive scheme has been drawn up which provides for increased accommodation for outpatients. The clinics are attended by a large number of physicians, British and foreign, interested in the study of nervous diseases. At one time much the most popular clinic was that of Sir William Gowers whose diagnosis of the most recondite nervous diseases was carried to a point seldom equalled and never surpassed. Now his place is taken by Dr. Risien Russell, who is equally popular and displays equal mastery of the subject and at a comparatively early age has attained a foremost position in British neurology.

PARIS LETTER.

(From Our Regular Correspondent.)

Paris, Dec. 5, 1908.

Special Diplomas.

When, about two years ago, there was created the certificate of higher medical studies, which every candidate for the *agrégation* or lowest rank on the medical faculties was to present, the medical profession unanimously protested. The decree was accordingly rescinded, but a "certificate of admissibility to the *agrégation*" was required instead. This did not relieve the situation. Yesterday a delegation from the Congress of Practitioners laid before M. Clemenceau, the prime minister, the energetic protest of the medical profession against a measure tending to create two classes of practitioners. M. Clemenceau declared that he agreed with the physicians, the obnoxious measure being in a way a re-establishment of the old *officiat de santé* (suppressed by the law of 1892).

The practitioners also demand the suppression of the special diplomas given in legal medicine, hygiene, etc. They maintain that the diploma of doctor in medicine ought to be the all-inclusive university degree, and that, as it calls for examination in legal medicine, hygiene, etc., new diplomas ought not to be issued after the doctorate. It is said, to be sure, that not all physicians possess the qualifications to become medicolegal experts. After carrying out the idea to its logical end, however, that is, after creating as many special diplomas as there are branches of medicine, the only thing left to do would be to suppress the degree of doctor of medicine. No doubt division of labor and specialization become daily more obligatory, in medicine as elsewhere; but to make good specialists it is not necessary to create special diplomas; it is necessary to give the students a good foundation of medical knowledge and then to leave each one to develop his special aptitudes. By the creation of special diplomas, the state seems to admit that the guarantees offered by the diploma of doctor of medicine are not sufficient. But, if this be true, it is the duty of the state to modify its system of medical instruction so as to exact better grounded knowledge from pupils.

Supplementary Medical Instruction.

Alongside of the official medical instruction given by the medical school, independent instruction tends to develop more and more in Paris. Thus, a certain number of physicians and surgeons of the hospitals organized last year an Association of Medical Instruction of the Hospitals. A private hospital, founded in 1903 for the special treatment of the victims of industrial accidents, has recently organized a course of instruction on industrial accidents, consisting of free public conferences intended for practicing physicians. They are obliged more and more by the law of 1908 to understand these questions, which enter in a great degree in daily medical practice. Professor Brissaud, Dr. Lucas-Championnière and others give lectures. A series of practical courses for practicing physicians and students will be given, under the patronage of the Catholic Institute of Paris, by a group of physicians and surgeons of the hospitals, former heads of clinics, internes and specialists. These courses will be essentially practical, being accompanied by examination of patients and treatment by students, presentation of instruments; they will comprehend the principal medical specialties.

A New Clinic Founded by Dr. Huchard.

Dr. Huchard has given an example to be followed. He is approaching the time of retirement from the Necker Hospital (the age of retirement is 65, and Dr. Huchard is now 64), but he feels that "repose is found through labor." He has therefore founded a clinic which will meet a need; for, though there are in Paris clinics of various kinds, there has been none up to the present for diseases of the heart and of the cardiovascular system. In creating the "Clinic for the Heart," Huchard intends to establish also a kind of dispensary for indigent patients. At the inauguration of the clinic last week, among a multitude of the friends and pupils of the master, the latter said: "I hope that other clinics may come into existence alongside of this one—that others, like me, may take the title of independent professor, and that an independent school of medicine may grow up in this corner of Paris."

BERLIN LETTER.

(*From Our Regular Correspondent.*)

Berlin, Nov. 12, 1908.

Medical Inspection of School Children.

Fifteen years ago a movement began in Germany to have the children of the public schools regularly supervised in respect to their health not only on their entrance into school, but also during their subsequent attendance, by school physicians, who are appointed by the local, not the national authorities. The published reports of the investigations of the medical inspectors have shown how useful and necessary this movement has been. It is thus made clear that the children of the poorer part of the population, for whom the public schools exist, very often fail to have recourse to medical aid in cases in which it is needed, partly from lack of the necessary means and partly from indolence, and for this reason diseased conditions result which might have been avoided by timely medical treatment. In consideration of this fact the oft repeated request of the medical profession to allow the pupils of the public schools to be supervised by official school physicians has been more and more complied with by the different communities after overcoming the initial difficulties which in many cities, especially in Berlin, were quite great. Now the number of communities which have regular medical inspection of the schools reaches into the hundreds. According to the character of their official position two systems of school physicians are to be distinguished, and regarding the comparative advantages of these systems unanimity has not yet been reached, not even among physicians.

The question under discussion is whether it is better to appoint a physician as school physician as his principal office, that is, to appoint a physician who is to a certain extent a specialist in school sanitation, and whose entire medical activity is restricted to this field, or to appoint a physician in a subsidiary office, that is, to entrust a general practitioner with the additional task of supervising the health of the school children. At the recent annual general medical convention, the Aerztetag, in June of this year, this question was thoroughly debated and the convention reached the following conclusion: In general the achievements in the field of school hygiene do not depend on the system under which the school physician is appointed, but on the personality of the medical inspector and on the improvement in the measures for the physical well-being of the school children. The question whether the school physicians shall be appointed to a principal office or a subsidiary office can not yet be settled at the present time; it depends on the amount of work required and on local and personal conditions. The convention also adopted a series of suggestions for the medical school inspectors, as follows:

1. The young should be familiarized in school with the rules of hygiene. A correct understanding of the rules of health is indispensable for their proper application. This leads to an improvement in the health, welfare and defensive strength of the people and increases thereby the public wealth.

2. In the education of all teachers for public and high schools, hygiene ought to form a special subject of instruction. For this instruction physicians are especially to be chosen as their education and profession guarantee appropriate instruction.

3. With every suitable study the pupils should be reminded of hygiene and held to a constant practice of its rules, but advice as to the treatment of diseases is not permissible. Articles on the care of the health should be introduced into the readers in the schools. For the preparation of such articles in the readers the cooperation of physicians is indispensable. The convention is not prepared to give an opinion regarding the cooperation of the school in instruction regarding sexual matters.

4. Special instruction in hygiene is particularly desirable for the older scholars. In the technical training schools the instruction in hygiene should be assigned to a physician. The appointment of school physicians in all schools will facilitate the carrying out of instruction in hygiene.

5. In order to carry out effectively the instruction and education of the youth of the schools the cooperation of physicians on the school boards is requisite.

An oversight of the work of the medical inspectors is afforded by the report of the Berlin school physicians for 1906-7, which recently appeared. In this year 44 school physicians were employed in the Berlin public schools. The number of scholars to be inspected amounted to 227,750. Each school physician had on the average 5.170 children under observation. At the examination of children entering the school for the first time, 3,100, i. e., 8.7 per cent., were excluded from attendance on grounds of health. Of those which were admitted, 9.169, i. e., 25.8 per cent., were placed under medical supervision on account of defects in health. During the year covered by the report, about 36,000 children were under the supervision of the school physicians. The number of supervised children has grown, little by little, because the appreciation of the value of such a supervision has increased both among the teachers and among the parents of the children. Among the newcomers rejected, 1,140 were excluded on account of debility, 158 on account of scrofula, and 172 on account of tuberculosis of the lungs. The same grounds gave occasion for continued supervision of about 10,000 children. As a result of examination by the school physicians, a considerable number of children were placed on account of their insufficient intellect in so-called side classes (*Nebenklassen*), in which the requirements with reference to progress in learning are less exacting. In addition, those hard of hearing or with defective vision were discovered and separated by the investigations of the school physicians. During the year 30 children were discovered who had to be transferred to an idiot asylum on account of their mental condition.

The Sale of Medicines.

In Germany the pharmacists are not allowed to sell every remedy freely, i. e., without a physician's prescription. A large number of medicines are excluded from free sale, the so-called hand-to-hand sale (*Handverkauf*), especially the direct and indirect poisons. These medicines, in case they have been dispensed on a physician's prescription, must not be given a patient a second time unless the renewal is sanctioned by a notice written on the prescription by a physician. The number of such medicines which are excluded from the free traffic of pharmacists naturally increases from year to year as the dangerous character of the newly introduced remedies is established. Thus to mention only a few, lysol, which has been a favorite means of suicide and is still so used, veronal and a number of so-called headache medicines are especially reserved for physicians' prescriptions. An article by an apothecary in a late number of the *Pharmazeutische Zeitung* is directed against the decree regarding headache medicines. He complains that almost all the headache remedies are already withdrawn from free sale, and the income of the apothecary is considerably reduced thereby. According to his opinion, there has not been so far any injury to health by the sale of headache powders, and it is not to be assumed that the public is disposed to go to a physician immediately for a simple headache. Such a complaint raised essentially in the interests of the business success of the pharmacists can not be too energetically combated. Not the income of the apothecary, but the welfare of the sick, is what is most important, and it is doubtless an erroneous claim that no injuries to patients have occurred from the dispensing of such remedies. Surely more cases of poisoning by antipyrin and similar medicines have occurred than have become known through the newspapers or the authorities. In the article of the pharmacist referred to, the very much-to-be-regretted fact appears that our pharmacists (as is said to be also the case in England and America) consider themselves as belonging less to the forces organized for the curing of disease than to the business world, and place money-making above their duty of service for the protection of health and overcoming of disease. So much the more is it the duty of the authorities and especially of the government to supervise the business of the pharmacists, in order to prevent injury in this line. Moreover, it is well known that quackery is carried on to a not inconsiderable extent in German pharmacies, notwithstanding the fact that the pharmacists deny this.

VIENNA LETTER.

(From Our Regular Correspondent.)

Vienna, Dec. 2, 1908.

The Steinhof Lunatic Asylum.

The new Steinhof Lunatic Asylum, which is said to be the largest and best equipped institution of this kind in Europe—perhaps also in the world—has just published its report on the first year of its existence. It consists of fifty-nine separate pavilions, and can accommodate 3,000 inmates. Unlike most free public asylums, it has one division, the sanitarium, which is expected to be self-supporting, for it is intended only for paying patients of the upper classes. This innovation has been received with great satisfaction by the public. Hitherto the only existing asylums were those intended for the lower classes, or the very expensive private homes resorted to by the upper classes. The pavilion system enables an individualized treatment to be given, and the rule is to bring only patients with similar affections in contact with each other.

Careful attention has been given to treatment by occupation. Large plots of arable land, much household work, and many professional occupations are in the hands of the patients, who seem to be doing it very well, and with benefit to their condition also. The milking of the cows and the care of the numerous gardens are all handed over to patients; even the printing of necessary papers is done by the insane.

The medical staff is comparatively small, consisting of 11 physicians, while 450 persons are employed on the nursing staff, the administrative body and in the household. The maximum number of patients allotted to a nurse is 12. The minimum air space per patient is 1,060 cubic feet in the wards, but the mean air space is 1,940 cubic feet per bed. Each pavilion has its own garden, separated from the common park by walls or railings. Heating is accomplished in the wards either by low-pressure steam or by tile stoves; light within the buildings is given by electricity, outside by gas.

As the grounds cover more than half a square mile, an electric tram is provided for. Good drainage is insured by the situation along the gentle slopes of a hill. The ventilation and the pure fresh air in the wards account for the good condition of the patients in respect to the respiratory organs. In fact, no case of disease has occurred which could not be ascribed to the mental condition of the patients. A mortality of only 8.5 per cent. was observed this year; but it must be remembered that many patients now there are suffering from general paralysis and other fatal diseases, and these will no doubt soon swell the mortality rate. The cost of the whole institution was $4,000,000 ($1,500 per bed), while the cost of maintenance is 80 cents a day per patient, against 50 to 70 cents in the general hospitals. The expenses are defrayed partly by the general government, partly by the local government of Lower Austria.

American Surgery as It Appears to an Austrian Surgeon.

In the *Wiener klinische Wochenschrift* Dr. Clairmont, assistant to Professor Eiselsberg, gives his impressions of American medicine, which he obtained on a trip to America for study. He visited the leading surgeons of Rochester (Minn.), Chicago, Baltimore and Philadelphia; watched them during operations, and noted the factors which have contributed to make American surgery so great.

Naturally, Dr. Clairmont had to employ as a standard of comparison the Viennese conditions with which he was familiar. Thus, he finds the absence of a pavilion system, due to the high price of ground, not so bad as might have been expected. American hospitals, founded and maintained by private munificence, compare very favorably in respect to liberality of equipment and comfort with European hospitals, founded and maintained by the state. The absence of gardens is a disadvantage for which roof-gardens do not compensate. The various city ambulance systems are said not to be so well organized as the *Rettungsgesellschaft* in Vienna. On the other hand, Dr. Clairmont was struck by the method of admission of in-patients and out-patients, and by the splendid organization of the hospital management, which often includes even a printing establishment for the hospital publications. The operating theaters, the separation between septic and aseptic operating rooms and the preparatory rooms disappointed Dr. Clairmont somewhat; but he says that European surgeons have much to learn from Americans in regard to economy of material, assistants and the nursing staff. The question of the nursing staff is a burning one on the continent of Europe. While American nurses come from good homes, European nurses come from the lower walks of life.

Dr. Clairmont pronounces the asepsis of American surgeons to be as perfect as possible; he obtained a very good impression from the small number of instruments required, even by the most eminent surgeons; and he also appreciated much the use of sterile water during operations. Anesthesia, which in America is induced mostly by ether, is there one of the most highly developed branches of surgical art: the care, exactness and gradual procedure struck the visitor very much. Dr. Clairmont saw the operations of Halsted, Cushing, Deaver, Mayo, Brewer and other eminent surgeons. He says that, as regards technic and practice, American surgeons are undoubtedly in the front ranks of the profession of the whole world. The abdominal operations of the brothers Mayo, the cerebral operations of Cushing, and the latter's experiments on animals especially elicited Dr. Clairmont's genuine admiration. He paid great attention to the position of American surgeons with reference to appendicitis and diseases of the liver and gall bladder; the methods and leading ideas of the foremost surgeons in America coincide with those of Eiselsberg and his school. Prostatic surgery is much advanced in America. Carrel's methods of suture and transplantation of blood vessels made a lasting impression on the visitor. A visit to the new medical school in Boston concluded Dr. Clairmont's stay in America. He returned some time ago, full of admiration of the achievements attained in surgery within the last few decades.

Pharmacology

"GETWELL TABLETS."

How the Anti-Cori-Zine Chemical Company Extends Its Business.

Physicians who are financially interested in the exploitation of questionable proprietaries (and happily we believe there are very few of these) usually excuse their course on the grounds that their preparations are advertised in medical journals, therefore they must be ethical. This placebo to professional conscience deceives no one, neither does it excuse, but it permits of a definite answer to an unpleasant question. With a "patent medicine" it is different. No physician who wishes to retain his self-respect desires to become in any way identified with so disreputable a business. It is not to be wondered at, therefore, that when a "patent medicine" firm is desirous of selling stock in its concern it leaves physicians severely alone.

Some of these concerns evidently believe that the dental profession does not share the feelings of the physician on this subject. At least that would seem to be a justifiable conclusion after reading some "form" letters sent to dentists by a Chicago broker.

> "Being a dentist, you are far enough removed from the position of professional jealousy (maintained by physicians) to see the subject in its practical light and I take it that profits made from 'patent medicines' are just as attractive to you as from any other source. . . . ."
>
> "All of this is by way of presenting an opportunity of sharing in the profits of one of the biggest earners in the *proprietary* field yet discovered. This is the Getwell Tablets. . . . . This tablet has been in use for 15 years in St. Louis among the practicing physicians. . . . ."
>
> "A year ago a company was organized among the most prominent *men of St. Louis (a city that boasts more big fortunes made* from patent medicines than any other in America) called the Anti-Cori-Zine Chemical Company. . . . ."
>
> "A campaign was made in Chicago and $10.000 spent in advertising. The success was phenomenal."
>
> "You doubtless know of the tremendous success made by the Antikamnia people of St. Louis, which has made the originator *many times a millionaire, to say nothing of the profits it made for* dentists who took the first stock. . . . ."

Then follows a statement of the amount of stock that is to be sold and a glowing prognostication of the vast profits to be made. With this "form" letter is another, purporting to be from the Anti-Cori-Zine Chemical Company to the broker, giving information about the financial standing of the company and its personnel.

> "The officers of this company are H. W. Hartwell, president (a physician of 25 years' practice in this city). A. D. Hartwell, secretary and treasurer (manufacturer of paints and varnishes). Joseph Griesedieck, vice-president (manager National Brewers' Assn., St. Louis). E. R. Rombauer, L.L.D. . . . ."
>
> "Our tablets are made under contract with Sharp & Dohme of Baltimore, Md. They cost us 65 cents per 1.000 and after boxing and preparation for the market, bring us $13.40 per 1.000."
>
> "You are no doubt acquainted with the splendid profits made on patent and proprietary medicines of this kind, such as Orangeade, [Orangeine?], *Cascarets, Bromo-Seltzer,* Bromo-Quinine, Laxative Pepsin, etc. . . . ."
>
> ". . . . The biggest fortunes in St. Louis have been made on patent medicines.. . . . ."
>
> "Profits in this business are far out of the ordinary and 400 to 600 per cent. is only normal. . . . This is true of every patent medicine of this nature. . . . ."

There seems to be no particular reason why this new acquisition to the ranks of the "subtle poisons" *should not* be a financial success. It apparently fulfills all the essential requirements of "patent medicine" ethics: (1) It has been in use for years *among practicing physicians* (a stock falsehood in this line of business); (2) its company has for its officers an M.D., a paint maker, a brewer and an LL.D.; (3) it is put up "under contract" by an old-line "ethical" house; and (4) there is 400 per cent. profit in it. It would seem that under such auspicious circumstances nothing but gross mismanagement can prevent the Anti-Cori-Zine Company from scoring a big success, as have many St. Louis firms in the same business.

As to the tablets themselves, they vary in no way from their prototypes and are advertised with that classic disregard for truth that characterizes nostrums of all classes.

> "No drug habit is formed by the use of Getwell Tablets, even when taken for long successive periods."
>
> ". . . . even persons suffering from the severest forms of heart disease can take them without the least danger."
>
> "The average dose is 3 for a man . . . . robust patients may require 1 or 2 more . . . taken at once and repeated in an hour if the mucous *discharge is not stopped.*"

The virtues of this wonderful tablet are due to our old friend, acetanilid, aided and abetted by another drug that is *becoming increasingly* popular with nostrum mongers—codein. Of the former there are practically 2 grains to the tablet; of the latter, 1/20 grain; there is also a small amount of belladonna. A "robust patient" may take—according to instructions—five tablets as a "starter" and five more an hour later. After thus devouring nearly 20 grains of acetanilid, his robustness might be somewhat impaired, but as this is a business proposition paying 400 per cent., one can hardly expect the Anti-Cori-Zine Chemical Company to mention it.

But Getwell is not the original name of the tablet; its earlier name was Anti-Cori-Zine, and as such it was sold to physicians.

> "Anti-Cori-Zine is an ethical preparation advertised only to the medical profession."

Like many another acetanilid mixture before the Food and Drugs Act spoiled the game, Anti-Cori-Zine was advertised as a "synthetic."

> "Anti-Cori-Zine is not a mere mixture of various remedies holding a reputation as cold cures, *but it is a definite, synthetic chemical.*" [Italics are ours.—Ed.]

Presumably an enlightened medical profession combined with a federal statute has caused the "synthetic" falsehood to become *stale, flat* and unprofitable, and there is now more money to be made in advertising to the public direct rather than via medical journals and physicians.

The medical profession should at least be glad to learn from an outside source that the "position of professional jealousy (maintained by physicians)" prevents it from looking on the "profits made from patent medicines" as "just as attractive" as those made in a more respectable line of business. The case of Dr. H. W. Hartwell, a homeopathic physician of St. Louis, and president of the Anti-Cori-Zine Chemical Company, seems to indicate, however, that the "position of professional jealousy" is not universally maintained. Doubtless the broadening influence of a financial venture that pays 600 per cent. enables him to rise above such petty things as "professional jealousy."

Testimonials or Alleged Clinical Reports.

At different times we have discussed the value—or worthlessness—of testimonials. As evidence, *their scientific value is nil;* as psychic stimulants, they rank high. It is for the latter quality that they are sought by the "patent medicine" and "*ethical proprietary*" exploiters. *Testimonials to "patent medicines"* are always paid for in an indirect way, though this *fact is not given any undue prominence. It has remained* for an English quack concern to come into the open and offer a spot cash remuneration for letters which detail the virtues of their goods. This is done by the "Dr." Gardner's Remedies, Ltd., of London, who advertise in the British press:

> "One Guinea each paid for every *bonâ fide* testimonial
> that is printed or used in any way as an advertisement, and
>
> *ONE HUNDRED POUNDS CASH*
>
> for the best testimonial received
> on or before December 1 next."

London *Truth*, a lay weekly that is aggressively exposing "patent medicine" frauds and quacks, says: "Any one who comes across in the newspapers, after this, surprising personal evidence of the miraculous effects of 'Dr. Gardner's Pink Tablets' or any other specific sold at the same shop will have no difficulty in accounting for the milk in the coconut."

To the initiated, the source of the milk has always been fairly evident, but it will be interesting to see whether the psychic—and only—value of the testimonial will be in any way weakened when the secret of its birth is a matter of public knowledge.

In the proprietary world a recent letter from the Manola Company to physicians shows a similar method of procuring testimonials. Not, of course, that they are called *testimonials*

—that would be too suggestive—no, "clinical reports" if you please, or "clinical data." Neither does the company offer to pay cash for such testimonials—that is to say "clinical data" —nothing so useful as money. Says the Manola Company:

> "We are now preparing a book containing clinical reports."
>
> ". . . we would like to have whatever clinical data you can give us in regard to your experience with Manola, even if it only covers one case."
>
> "As a token of our appreciation of such a report we will send you three full-sized bottles of Manola, express prepaid, for your personal use."

In the future, "personal evidence of the miraculous effects" of Manola will—at least to the initiated—at once conjure to one's mental vision three bottles of Manola! Isn't this pretty cheap? Those addicted to the testimonial habit have, therefore, three schedules: Lehn & Fink's,[1] $10.00 a page; the Manola Company, 3 bottles a report; and "Dr." Gardner's, from 1 guinea to 100 pounds. ($5.00 to $500.00) a testimonial. From a purely business standpoint, it would appear that the out-and-out "patent medicine" firm offers the highest inducements.

The Manola people are evidently profiting by past experience. They it was who conceived the idea[2] of getting the physician to act as a peddler for Manola, and at the same time force the druggist to fill up his shelves with their stuff. The price for this service also, was—three bottles!

Will the time ever come when the medical profession will administer such a rebuke to firms of this type that fear of commercial annihilation will compel in them that regard for decency which less drastic methods seem unable to effect?

Emanosal and Radium.

When the remarkable properties of radium were discovered, the "patent medicine" ranks were soon swelled by a number of "radium cures." Then came the Food and Drugs Act, which interfered with the quack's "personal liberty" to the extent of insisting that he must not tell a barefaced lie on the label. This made "radium cures" flat, stale and unprofitable, and the proprietors thereof either dropped the "patent medicine" business for a more respectable one or perhaps turned their talents toward headache powders or eye lotions.

Meanwhile radium and other radioactive substances were being studied scientifically and a large amount of data accumulated. It was found, for instance, that water can be charged with radium emanations. As a corollary some one formulated the brilliant theory that possibly the therapeutic value of certain springs is due to their impregnation with radium emanations. The fact that water soon loses its radioactive properties was made to explain why the water of these same springs ceases to have any medicinal virtue when transported.

It is now claimed that the emanations can be made portable by combining them with certain salts. These salts when dissolved in water artificially radioactivate that fluid which, as a therapeutic (?) agent, can be used either internally or externally. Even had these radioactivated salts any therapeutic value, their use in the form of tablets for producing radioactive solutions, however attractive as a method of medication, is one that is open to serious objections. Such tablets deteriorate rapidly, even when honestly made. To the unscrupulous maker, their manufacture offers a wide field for sophistication, as it is not an easy matter to determine their radioactivity.

To ascertain the character of certain preparations on the market, Professor Herbert N. McCoy, of the University of Chicago, an authority on the subject of radioactivity, on our request, made an examination of two kinds of tablets. Of the first he reports: "They are faintly radioactive as compared with uranium. They consist essentially of common salt and powdered pitchblende. After dissolving the former in water, there was left a black insoluble residue of rather coarsely powdered pitchblende (a mineral essentially U_3O_8, which always contains a small proportion of radium). Each tablet contains 0.18 gm. (3 grains) of pitchblende worth 1/10 of a cent."

The second sample of tablets was from a reliable manufacturer, Farbwerke vorm. Meister Lucius & Brüning. This firm aserts that its preparation, "Emanosal," contains the radium emanation in an absolutely permanent form. According to Laqueur, these tablets when fresh, equal 8,000 units of radioactivity, though Nagelschmidt has found them to vary between 2,000 and 5,000 units. Professor McCoy reports that these tablets were completely soluble in water and consisted largely, or wholly, of salt and sodium carbonate. They were faintly radioactive and about 1.5 per cent. as active as an equal weight of pitchblende. Each tablet has an activity equal to that of $6x10^{-8}$ gm. of radium. To put it another way: If radium is worth $2,325,000 an ounce ($75 a milligram) each tablet contains about ½ of a cent's worth of radium. They sell for fifty cents each.

It is surprising that enterprising quacks have not put on the market similar tablets. They could still tell the truth on the label and at the same time make a comfortable profit.

Correspondence

Bovine Necropsy as Object Lesson on Importance of Tuberculin Diagnosis of Tuberculosis.

MARSHALLTOWN, IOWA, Dec. 5, 1908.

To the Editor:—In response to your request for information and description of a demonstration on a cow affected with tuberculosis, which took place in our city last February, I am pleased to give the following particulars:

I have been much impressed by statistics showing the prevalence of tuberculosis among the farming classes. In corresponding with the bureaus of animal industry of the experimental stations of our own and other agricultural states of the middle west, I also noticed the increase and widespreading prevalence of tuberculosis among cattle and hogs. This induced me to study the relations between bovine and human tuberculosis. For instance, in the statistics of tuberculosis of the Board of Control of State Institutions for 1906, out of 5,469 cases reported—which does not mean complete statistics of the state—the housewives head the list with 1,101 cases; next come the farmers, 657 cases; farmers' wives, 100 cases; sons and daughters, 83 cases—a total from rural life of 840 cases. These latter cases far outnumber those of any single occupation other than that of housewife or of several other occupations together. Why should tuberculosis be so prevalent in country life? The more I study statistical reports on tuberculosis, the more I am convinced that bovine tuberculosis is a great factor in the wide prevalence of tuberculosis in the human race. Therefore, I have become an ardent advocate of the elimination of bovine as well as human tuberculosis.

In August, 1907, being a member of the city council and local board of health, I introduced an ordinance, which was passed, providing that "whosoever within the corporate limits of the City of Marshalltown, Iowa, shall offer for sale milk or products of milk—cream or butter—shall first procure a license, previous to the granting of which he shall state in writing the number of cows, his place of residence, and whether he procures milk from other source than his own dairy"; and that "the mayor shall appoint a veterinarian in good standing with the State Board of Health, who shall immediately proceed to test all cows or other cattle on premises, unless wholly isolated from milk cows, with what is known as the tuberculin test for tuberculosis."

This, of course, seemed to the owners of milk cows a radical measure, and a storm of protests arose. The dairymen organized, secured legal advice, and threatened suits. I sought to allay prejudice by argument, and suggested to the veterinarian and mayor, who were heartily in support of the measure, that it would be useful to explain to the public the lesions of tuberculosis in animal tissues by slaughtering and exposing the carcass of a cow which by previous tuberculin test had been shown to be affected with tuberculosis. Thus many might be convinced that the use of milk, cream or butter from a cow sick with tuberculosis—or any other disease, for that matter—was dangerous to the health and should be prohibited. The announcement of the test and demonstration created much interest. The occasion was auspicious, as a short course in grain and stock judging and domestic science was being given for farmers under the auspices of the Iowa State Agricultural College.

---

[1] THE JOURNAL, Feb. 29, 1908.

[2] THE JOURNAL, May 6, 1905.

The cow on which the demonstration was to be made had been condemned a few days previously by the city inspector, after showing a decided reaction from the tuberculin test. The animal's appetite had been good, and it had been furnishing milk for one of the regular routes of the city. In appearance its physical condition did not indicate disease, especially tuberculosis, as pictured in the minds of most people. The hair was smooth and the submaxillary and superficial glands were not enlarged. When the abdominal cavity was opened a good supply of fat was noticed. There was no enlargement of mesenteric glands, but the liver presented an irregular surface and was the seat of several tuberculous areas of compact nodules, yellowish-gray in appearance. One especially large deep-seated mass of tubercles was bisected and revealed that dense characteristic change in tissue formation of the tuberculous nodule; the central portion had become caseous, and before long, disintegration would have taken place. The spleen also was the seat of numerous small tubercles the size of a split pea and somewhat larger, hard and uneven to the touch, with the same characteristic appearance as those of the liver. The lung tissue was somewhat pale in appearance and there was tuberculous infiltration in the middle and upper lobes of the right lung. Numerous large and small grayish tubercles seemingly blocked air spaces. Many of these on cross section had a caseous appearance. One large cheesy mass, three inches in diameter, circumscribed by thin walls, was found in a state of softening, almost to liquefaction and cavity formation, near the posterior and upper portion of middle right lobe. These gross lesions were readily seen without a microscope. There were numerous other lesions in various stages; the deep glands on the posterior surface of the pleural cavity were enlarged. The glands of the udder were not enlarged or affected, as determined without section. Dr. J. H. McNeil, head of the division of veterinary medicine of Iowa State Agricultural College, gave an interesting lecture on bovine tuberculosis, the method of obtaining tuberculin, its harmlessness, and its great value as a diagnostic remedy in tuberculosis. A profound impression was made and the dairymen who had previously organized to fight the ordinance requiring the tuberculin test ceased their opposition and gave their assistance to the city council in its efforts to secure enforcement of these necessary precautions. The news of the demonstration, we believe, has gone far and created much interest in outside communities, as frequent requests for information from cattle men and city councils are received.

W. S. Devine.

Bound Volumes of The Journal—A Proposition on Which Comments Are Desired.

Montecito, Calif., Dec. 2, 1908.

To the Editor:—I have a proposition for the consideration of The Journal, and incidentally for criticism by members of the Association. The Journal is naturally that medium which first brings to the notice of the bulk of the profession anything that is new in the science of medicine. We read the results of investigations first as news and later, as we wish to apply them in our own practice, we look up the back numbers of The Journal to refresh our memory. It seems to me that this reference feature of the paper has never been adequately emphasized and exploited, as compared with its other function of new-giving. I am of the opinion that on reflection most members will admit that the former is as important as—is, in fact, the complement of—the other.

The man who is throwing aside his copies of The Journal after the first perusal is getting but a tithe of that for which he is paying, that which is rightly his. The news items, the latest discoveries in various lines of research, pass weekly through our cerebral clearing-house and are there sorted into their respective pigeon holes, forgotten or remembered as they appeal to the interest uppermost in each of us. We can remember the general drift of an epoch-making discovery, but the details, that painstaking attention to minutiæ which is the inevitable requisite condition of success, are too elusive for human memory.

The text-books, at best, give us a bare historical account of results attained, summed up dispassionately long after the fight. Our weekly Journal, on the other hand, shows the battle in detail as by vivid pen-pictures of a war correspondent; obstacles and difficulties, now appearing insuperable, now yielding before well-directed onslaught. There is as much difference between reading in the morning newspaper the bare score of a championship university football game and seeing from the bleachers the actual contest itself. All matters relating to medical progress the bound volume of The Journal offers in graphic chronologic sequence, months, often years, before any text-book on the subject is published.

Why, then, do we not bind our Journals? For most of us this binding proposition has been something of a nightmare, and we can scarcely be blamed if many of us have shirked it altogether, or (paving a certain road with good intentions) have put it off from year to year. To the successful busy practitioner the semi-annual hunt for the two or three copies mysteriously but inevitably missing—the search for a local bindery (it is incredible how scarce good binders seem), the transportation of The Journals to and fro, the explanations, the cost in money and (what matters more) in time, and last, but not least, the futile effort to have the product of this year look like a creation of at least the same generic species as the abortion the peripatetic binder turned out for us a six-month ago, all these are small worries which surely one is justified in evading, even perhaps at the cost of a ready reference library.

Now, why can not the management of The Journal take this load off our shoulders (and our consciences)? It is in a position to do it for us far better than we can do it for ourselves, and incidentally save us all further thought in the matter. The few extra dollars with the annual subscription will never be felt.

Figure it out as a business proposition, from the point of view of the doctor. Put on one side the trifling additional cost a mere bagatelle to any of us—and the few strokes of the pen requisite in making out a check for a larger amount. On the other side, put the time wasted, as just pictured, which could be profitably spent in our practice or our recreation. There are few of us to whom time is not the most valuable commodity we possess; yet the time is the smallest part of it. There is the mental effort, the knowledge in our subconsciousness that in a few months or weeks we ought to be tackling that pile of dusty journals disarranged by many hunts for So-and-So's article about the treatment for such-and-such. This is an age of specialism; in nothing more so than in medicine. Yet we have allowed others to take the lead of us in this direction. This idea of mine is not mine at all. Like Kipling's Homer:

> "And what 'e thought 'e might require,
> 'E went and took—the same as me!"

I just stole it. For years it has been the custom of certain magazines, particularly the foremost yachting paper, the *Rudder*, to offer at the end of one year the bound volume, with the subscription for the forthcoming year at an inclusive rate. In the instance mentioned the plan has worked admirably; so why should not The Journal of the American Medical Association make us a similar proposition?

As to the price, $12 has been suggested for the current subscription and the two half-yearly bound volumes—$3 being the regular price for binding the two volumes. Why not make it $13, making use of the low prepaid book rate, shipping the completed volumes, express paid, to the subscribers? It seems to me that this can not fail to appeal to the majority of the members of the Association. When the blanks are sent out for subscriptions, why not have a separate line which allows one to subscribe $13 instead of the old-time $5 for The Journal for 1909 and the two bound volumes for the same year when completed, delivered, express prepaid?

Julius H. Hurst.

[Comment.—The Journal will be pleased to have an expression of opinion from its readers as to this proposition. A postal card will suffice.—Ed.]

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF ORGANIZATION, POSTGRADUATE WORK, CONTRACT PRACTICE, INSURANCE FEES, LEGISLATION, ETC.

County Secretaries Meet in Michigan.

In the *Journal of the Michigan State Medical Society* for November appear the proceedings of the first annual meeting of the Association of County Secretaries of the Michigan State Medical Society, held at Detroit, Sept. 30, 1908. Thirty-six county and state officers devoted the afternoon and evening to a discussion of the practical problems of medical organization, seven papers being read and discussed.

Dr. A. E. Bulson, Jackson, Councilor for the Second District, spoke on "Medical Organization, What It Has and Should Mean in Michigan." The history of medical organization in Michigan was reviewed and present conditions contrasted with those which existed prior to reorganization. Dr. Bulson also discussed medical legislation, the value of postgraduate work, the importance of medical students receiving instructions in medical ethics and the possibilities of improvement in medical society work in the future.

Dr. C. S. Oakman of Detroit spoke on the scientific work of county societies, emphasizing the importance of attractive programs and advising that the program be made out for an entire season in advance: that "text-book papers" be avoided and that papers be illustrated wherever possible. Symposiums were regarded as of value whenever the subject is broad enough to warrant them. The value of frequent notices and of printed programs for meetings was also emphasized.

Speaking on the "Social Features of the County Program," Dr. C. D. Morris of Pontiac related the experience of his own county society in supplying the social needs of its members. An extended discussion followed, various secretaries present relating their experiences.

An excellent paper on "The Business Side of the Secretary's Work" was read by Dr. A. S. Kimball, Battle Creek. Some of his conclusions should be considered by every county secretary. Briefly summarized, they were: Keep the society's business independent of your own business affairs. Maintain a separate account for each member as well as a separate cash account showing all collections and expenditures. Before the annual meeting have each account posted to date and dues for the new year entered so that members can pay at once and receive proper credit. The nightmare of the secretary's official existence is the collection of dues. Persistency and tact are two qualities absolutely essential for the successful county secretary. It is as tiresome to hammer a physician for his dues as it is to dun a patient for the payment of services long since rendered. Never draw a cent out of the society's account save by check, so that your returned vouchers will check up with your final account. If the county secretary fails to report a member in good standing, he will probably be placed under the ban by the state secretary. While county secretaries have their troubles in keeping local members in line, the state secretary has his, greatly multiplied. In order to do justice to all, the county secretary should, immediately on the receipt of the member's dues, remit them to the state secretary. With close application and systematic methods, many of the petty embarrassments and unpleasant features of the county secretary's work would disappear.

County secretaries are middlemen, buffers alike for state secretary and member. Prompt, businesslike dealings with both will make their position far more pleasant. "We, as secretaries, must then, first of all, inaugurate system into our whole work; promptness both in our dealings with the state society and local members; maintain, or if necessary, cultivate patience, persistency and diplomacy in our dealings with our fellow-members, and practice the strictest economy in our dealings with others for the good of our society bank account; and, finally, account in a clear and concise way for our year's work at the annual meeting." The protracted discussion which followed Dr. Kimball's paper showed that questions relating to the business management of the society were regarded as vital to the progress of the organization.

Dr. J. C. Johnson, Lenawee, spoke on "New Members and Attendance," emphasizing the importance of personal invitations to each non-member and especially to those who have recently located in the county.

Dr. C. S. Cope, Ionia, under the title "What Can be Accomplished by Hustling," reviewed previous experience in medical organization in his county, and related the methods used in interesting the physicians in medical organization during and after the reorganization period. Letters were sent to every physician in the county who could not be reached by personal visitation. A few lines calling attention to the coming meeting and inviting attendance and cooperation were repeated from time to time. A tasteful, inviting program was printed for each meeting and a copy sent to each member, efforts being made to have each program contain some unique and attractive feature. Special efforts are also made to have the meetings bright, attractive, and as short as is consistent with thoroughness. Long drawn-out discussions and stilted parliamentary sittings are avoided. Frequent banquets and luncheons are held, the physicians of the town in which the society meets generally acting as hosts. On the secretary falls the burden of originating and carrying out plans that will attract and hold the members, and unless he is self-sacrificing and willing to do all the work, he had best not accept the office, for without these necessary qualifications, he will be a failure. "The man to whom the county medical society most appeals and whom it is designed to benefit is the county doctor. . . . It is to reach him, to bring forth the best that is in him . . . . that the society and the secretary must bend every effort. This is no boy's play. It will weary you, tax your ingenuity to the utmost, but you will reap a glorious harvest if you are faithful to the trust given you."

At the dinner given in the evening, an especially valuable paper was read by Dr. B. R. Schenck, the state secretary. Dr. Schenck took as his subject "The Michigan State Medical Society—What, When, Where, Why, and How It Is," the object being to explain to the county secretaries of the state the exact relation existing between the county and state societies and the national Association; what constitutes membership and why certain methods were necessary. Considering what the state society is, Dr. Schenck said: "The center of the communal life of physicians is the county society. It is to the local organization that the individual physician owes his first allegiance. If the local organizations are supported and built up into what they are capable of becoming, there may be no fears as to the prosperity of the state or national organizations. The state association is but the aggregate of the county societies' activities. It is the sum total of effort and achievement, as manifested in the local organizations. The influence of the state society is great, but compare its influence with that vast influence which is exerted by our fifty-five active county societies, meeting weekly, bi-weekly, monthly or quarterly. There are scheduled for the counties of this state during the coming year, 392 different meetings with an attendance which I have very conservatively estimated at 7,250. The state society is the aggregate—it is the great centripetal force that binds these 55 units together, keeping them working in harmony, supplying ideas and new motives. . . . It is the conception of the state society as merely a body of men which meets yearly for a two days' session of scientific and social intercourse and lying dormant between whiles, which I wish to combat. Our state society exists every day in the year in our county societies."

Considering the question why the state society exists, Dr. Schenck quoted from the constitution of the state society and showed that out of 4,200 physicians in the state, there were 1,975 paid members, being 47 per cent. of the physicians of the state, or about 63 per cent. of those eligible to membership. The objects of the state society are to extend medical knowledge and advance medical science; to elevate the standard of medical education; to guard the material interests of the physicians of the state and to enlighten and direct public opinion on great problems of state medicine. While these purposes are being partially carried out, opportunities are being wasted, which, if grasped, would show the profession becoming more capable and honorable within itself and more useful to the public in the prevention and cure of disease and in prolonging and adding comfort to life.

Under the heading, "How the State Society Is," Dr. Schenck discussed in detail the points of contact between his work and that of the various county secretaries, enumerating the methods used for regulating membership and showing how necessary it is for the successful working of the organization that every official should do his part promptly and accurately. A critical discussion of the state journal closed this most valuable paper.

The above synopsis is given, not only because many of the ideas brought out by the speakers were of great practical value, but also in the hope of encouraging other state secretaries to provide for annual meetings of the secretaries of county societies and the general officers of the state association. As our organization grows and as our various lines of work become more and more complicated, the necessity for accurate, prompt and effective cooperation between the different parts becomes more apparent. A single inefficient, careless or delinquent executive officer in any part of the organization can cause much unnecessary work and vitiate the results of the good work which is done by others. It is imperative that the clearest understanding and the closest cooperation should exist between the state society and the various county societies; that the county secretary should understand clearly why certain things are expected of them and how these things can best be done. In no way can this be so readily accomplished as by conferences held at least annually and, preferably, semi-annually. Already, a number of our states, notably, Pennsylvania, Ohio, Iowa and Illinois, have held such conferences. It is to be hoped that their example will be followed by other states until these meetings will become an established part of our yearly work.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES.

DR. JOHN H. BLACKBURN, DIRECTOR.
Bowling Green, Kentucky.

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

DISEASES OF PENIS.

Phimosis.—Congenital, acquired. Indications for circumcision. Technic. Complications.

Paraphimosis.—Causes. Treatment, reduction, incision.

Wounds of Penis.—Contused, incised, lacerated. Dangers, hemorrhage, injury of urethra, infection.

Fracture of Penis.—Causes, prognosis, treatment.

Inflammations.—Acute and chronic, causes, prognosis.

Balanitis and Balanoposthitis.—Diagnosis, treatment.

Herpes Progenitalis.—Causes, diagnosis, differentiation.

Tumors of Penis.—(a) Verrucæ or papillomata; pathology, causes, diagnosis. (b) Epithelioma; symptoms, diagnosis, extension, treatment. Technic of partial amputation, of complete amputation.

DISEASES OF THE URETHRA.

Hypospadia.—Balanic, penile, perineal; defects associated with each. Indications for treatment.

Epispadia.—Associated malformations. Treatment.

Wounds of Urethra.—Surgical or accidental. Incised, lacerated, contused, punctured. Complications, treatment.

Rupture of Urethra.—Causes in (a) penile, (b) perineal portion. Partial or complete. Symptoms, hemorrhage, tumor formation, pain, retention of urine. Complications, hemorrhage, retention and extravasation of urine, false passages, sloughing, fistula, stricture. Treatment: palliative, operative, posterior or retrograde catheterization.

Foreign Bodies and Calculi.—Diagnosis, treatment.

Urethritis (Non-venereal).—Predisposing causes: (a) Diathetic conditions, (b) chronic urethral disease, (c) morbid states of urine, (d) sexual abuses, (e) dietetic excesses, (f) alcoholism. Exciting causes: (a) Trauma, (b) bacteria (non-specific), (c) toxins, (d) chemical irritation, (e) sexual strain.

Fifth Month—Third Weekly Meeting.

DISEASES OF THE BLADDER.

Exstrophy.—Cause, associated defects, associated pathology. Treatment, palliative, operative.

Hypertrophy and Atrophy.—Causes, diagnosis, prognosis.

Wounds of Bladder.—Contused and lacerated, gunshot. Intraperitoneal, extraperitoneal. Symptoms: Urine in wound, straining urination with blood or bloody urine, probe into bladder or urethral sound out through wound, shock. Complication: Hemorrhage, peritonitis, cellulitis, fistula.

Rupture of Bladder.—Causes: (a) Predisposing, distention, alcoholism, adhesions from cellulitis, chronic cystitis. (b) Exciting, fractures, muscular strain, fall on ischium, acute retention, injections. Pathologic rupture. Intraperitoneal and extraperitoneal rupture. Symptoms: General and local, physical signs. Treatment, after-treatment.

Cystitis.—Etiology: Predisposing, congestion of bladder due to (a) retention, (b) trauma, (c) abnormal muscular contractions, (d) abnormal urine, (e) tumors and calculi, (f) cold, (g) sexual excesses, (h) cardio-vascular disease, (i) cerebrospinal lesions. Exciting cause, local infection, extension, organisms found. Pathology: (a) Catarrhal, (b) interstitial, (c) membranous, (d) gangrenous.

Tuberculosis, Calculi and Tumors of Bladder.

Tuberculosis.—Infection (Koch): 1. Bacilli in body; (a) through blood current, (b) by lymph channels, (c) excretion of bacilli, with or without nephritis. 2. Bacilli from without: (a) by cohabitation, (b) by catheterism. Pathology: Pericystitis, changes in wall, mucous membrane. Symptoms: Onset, hematuria, pyuria, pain, general symptoms. Microscopic examination of urine, cystoscopy.

Vesical Calculi.—Varieties: Uric and uratic, phosphatic, calcium oxalate and carbonate, cystin. Etiology: Age, sex, drinking water, geographic distribution. Symptoms: Frequent urination, pain, hematuria, reflex disturbances. Treatment: Preliminary, litholapaxy, lithotomy, perineal and suprapubic.

Tumors.—Classification and etiology: (a) Benign, papilloma, adenoma, fibroma, myxoma, cysts; (b) malignant, carci- cystoscopic appearance, in each. Symptoms: Hemor- noma, sarcoma, mixed tumors; frequency, site, number, attachment, infiltration, lymphatic involvement, age, sex, rhage, pain, frequent urination, fragments of tumor.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Dec. 12, 1908:

Kulp, John S., maj., retired from active service on account of disability, Dec. 4, 1908.

Truby, A. E., maj., detailed member of examining board at San Francisco, vice Col. G. H. Torney, relieved.

Kiersted, H. S., capt., granted leave of absence for one month, about Dec. 15, 1908, with permission to apply for an extension of 15 days.

Kendall, W. P., major, granted leave of absence for 10 days.

Worthington, J. A., lieut., assigned to duty on transport *Thomas*, instead of transport *Crook*.

Pinkston, O. W., lieut., when services are no longer needed on transport *Crook*, ordered to Hot Springs, Ark., for duty at the Army and Navy General Hospital.

Nichols, H. J., lieut., granted leave of absence for two months, on arrival in United States.

Lewis, W. F., maj., relieved from duty at Ft. Sill, Okla., and ordered to Ft. Thomas, Ky., for duty.

Pierson, R. H., capt., ordered from Ft. Niagara, N. Y., to Ft. H. G. Wright, N. Y., for temporary duty.

Byrne, C. B., col., ordered to report before Army retiring board at Washington, for examination.

Mount, J. R., M. R. C., leave of absence revoked.

Sparrenberger, F. H., M. R. C., relieved from duty at Ft. Washakie, Wyo., and ordered to Ft. Warren, Mass., for duty.

Brewer, I. W., M. R. C., when relieved from duty at Ft. Warren, Mass., ordered to San Francisco, and thence to sail for service in the Philippine Islands.

Johnson, C. W., M. R. C., ordered from Ft. Des Moines, Ia., to Ft. Meade, S. D., for temporary duty.

Smith, R. D., M. R. C., relieved from further duty in the Philippines Division.

Stallman, G. E., dent. surg., left Ft. Logan H. Roots, Ark., for duty at Ft. Sill, Okla.

Whinnery, J. C., dent. surg., left Ft. Case, Wash., for duty at Ft. Ward, Wash.

Tignor, E. P., dent. surg., left Governor's Island, N. Y., for duty at Ft. Howard, Md.

Ratliff, L. H., cont.-surg., contract annulled Nov. 26, 1908.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending Dec. 12, 1908:

Carpenter, D. N., surgeon, ordered to the Naval Academy.

Warner, R. A., P. A. surgeon, detached from the Naval Academy and ordered to duty at the naval hospital, Norfolk, Va.

Eytinge, E. O. J., asst.-surgeon, detached from the *Ranger*, when placed out of commission, and to duty at the naval hospital, New York.

Geiger, A. J., P. A. surgeon, detached from the naval station, Guam, L. I., and ordered to the *Supply*.

Casto, D. H., asst.-surgeon, detached from the *Supply* and ordered to continue duty at the naval station, Guam, L. I.

Thomas, G. E., acting asst.-surgeon, appointed acting assistant surgeon from Dec. 3, 1908.

Munson, F. M., P. A. surgeon, ordered to the *Monadnock* and *Monterey* when discharged from treatment at the naval hospital, Canacao, P. I.

Downey, J. O., asst.-surgeon, detached from the *Relief* and ordered to the *Charleston*.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine-Hospital Service for the seven days ended Dec. 9, 1908:

Blue, Rupert, P. A. surgeon, granted 4 days' leave leave of absence from Dec. 9, 1908.

Billings, W. C., P. A. surgeon, Bureau orders of Nov. 28, 1908, amended and directed to report to the superintendent of the Revenue Cutter Service School of Instruction, Dec. 2, 1908.

Goldberger, Joseh, P. A. surgeon, granted 1 day's leave of absence, Dec. 3, 1908, under paragraph 191, Service Regulations.

Sweet, E. A., P. A. surgeon, granted 1 month's leave of absence from Nov. 25, 1908, on account of sickness.

Sweet, E. A., P. A. surgeon, relieved from further duty at San Diego, Cal., on arrival of Surgeon Paul M. Carrington, Dec. 2, 1908.

Hurley, J. R., asst.-surgeon, granted 10 days' leave of absence from Dec. 6, 1908.

Kastle, Joseph H., Chief Division of Chemistry, Hygienic Laboratory, detailed to represent the Service at the annual meetings of the American Physiological Society and the American Society of Biological Chemists to be held at Baltimore, Md., Dec. 28, 1908, to Jan. 2, 1909. Dec. 4, 1908.

Bowie, Robert I., sanitary inspector, granted 6 months' leave of absence from Feb. 1, 1909, without pay.

Branham, H. M., acting asst.-surgeon, granted 4 days' leave of absence from Nov. 10, 1908.

Foster, S. B., acting asst.-surgeon, granted 23 days' leave of absence from Dec. 6, 1908.

Gibson, L. P., acting asst.-surgeon, granted 5 days' leave of absence from Dec. 2, 1908.

Hallett, E. B., acting asst.-surgeon, granted 2 days' leave of absence from Dec. 9, 1908.

Light, S. D. W., acting asst.-surgeon, leave of absence, granted Nov. 18, 1908, for 22 days from Nov. 17, 1908, amended to read 30 days from Nov. 18, 1908. Dec. 4, 1908.

Nute, A. J., acting asst.-surgeon, granted 14 days' leave of absence from Dec. 16, 1908.

Tappan, J. W., acting asst.-surgeon, granted 10 days' leave of absence en route to station. Dec. 5, 1908.

Wilson, J. G., acting asst.-surgeon, granted 3 days' leave of absence from Dec. 6, 1908, under pargraph 210, Service Regulations.

BOARD CONVENED.

Board of medical officers convened to meet at the Marine-Hospital in Baltimore, Md., Dec. 7, 1908, for the purpose of conducting a physicial examination of a cadet of the U. S. R. C. S. Detail for the board: Surgeon W. P. McIntosh, chairman; P. A. Surgeon W. C. Billings; and P. A. Surgeon J. W. Schereschewsky, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended Dec. 11, 1908:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 15-21, 3 cases.
Illinois: Springfield, Nov.27-Dec. 3, 1 case.
Indiana: Lafayette, Nov. 15 30, 6 cases.
Kansas: Topeka, Nov. 22-28, 13 cases.
Kentucky: Covington, Nov. 22-28, 13 cases.
Maine: Saint David, Nov. 22-28, 1 case.
Michigan: Grand Rapids, Nov. 15-21, 1 case; Saginaw, Nov. 22-28, 3 cases.
Montana: Butte, Nov. 4-17, 7 cases.
Ohio: Cincinnati, Nov. 21-27, 1 case.
Texas: San Antonio, Nov. 22-28, 2 cases.
Vermont: Bellows Falls, Dec. 4, 1 case; Brattleboro, Nov. 1-Dec. 4, 60 cases; Dummerston, 2 cases; East Dover, 22 cases; Putney, Dec. 4, 1 case; South Londonberry, Nov. 1-Dec. 4, 2 cases; West Charleston, Dec. 4, 1 case.
Wisconsin: LaCrosse, Nov. 22-28, 5 cases; Manitowoc, Nov. 15-21, 25 cases; Milwaukee, 3 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Oct. 18-24, 5 cases, 2 deaths.

SMALLPOX—FOREIGN.

Arabia: Aden, Nov. 2-9, 2 deaths.
Brazil: Para, Oct. 25-Nov. 7, 2 cases, 1 death; Rio de Janeiro, Oct. 19-25, 411 cases, 190 deaths; Santos, Oct. 5-18, 17 cases, 5 deaths.
Canada: Charon Brook, Nov. 22-28, 1 case; Edmunston, 5 cases; Halifax, Nov. 15-21, 1 case; Kingston, 40 cases; St. Anne Quisibis, Nov. 22-28, 1 case; St. Basil, 4 cases.
Egypt: Cairo, Oct. 15-21, 5 cases.
France: Paris, Nov. 8-14, 3 cases.
India: Bombay, Oct. 27-Nov. 3, 1 death; Calcutta, Oct. 11-17, 2 deaths.
Italy: General, Nov. 8-15, 34 cases; Genoa, Oct.1-31, 7 cases; Naples, Nov. 8-15, 18 cases, 1 death.
Java: Batavia, Oct. 11-24, 4 cases.
Mexico: Mexico City, Oct. 4-17, 6 deaths.
Norway: Christiania, Nov. 1-7, 1 case.
Russia: Moscow, Oct. 18-Nov. 14, 55 cases, 25 deaths; Riga, Nov. 8-14, 2 cases; St. Petersburg, Oct. 21-27, 8 cases; Warsaw, Oct. 18-21, 12 deaths.
Spain: Barcelona, Nov. 11-21, 29 deaths; Seville, Oct. 1-31, 1 death; Valencia, Nov. 1-14, 5 cases; Vigo, Nov. 1-7, 1 death.
Turkey: Constantinople, Nov. 9-15, 5 deaths.
Zanzibar: Zanzibar, Oct. 24-30, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Oct. 10-24, 95 cases, 44 deaths; Provinces, Oct. 10-24, 1,534 cases, 864 deaths.
India: Calcutta, Oct. 11-17, 17 deaths; Madras, Oct. 23-30, 4 deaths.
Russia: General, to Oct. 25, 25,509 cases, 11,962 deaths; St. Petersburg, Oct. 26-Nov. 1, 19 cases, 22 deaths; Riga, Nov. 8-14, 2 deaths.
Straits Settlements: Singapore, Nov. 25-31, 2 deaths.

YELLOW FEVER.

Brazil: Manaos, Oct. 25-31, 1 death; Para, Oct. 25-Nov. 7, 5 cases, 5 deaths.
Ecuador: Guayaquil, Oct. 24-31, 1 death.
Mexico: Mexcanu, Oct. 14-21, 1 case; Merida, Nov. 15-21, 1 case.
Martinique: Fort de France, Nov. 1-7, 1 case, 1 death.

PLAGUE.

Brazil: Rio de Janeiro, Oct. 19-25, 8 cases, 6 deaths.
China: Tongshan and vicinity, Aug. 20-Oct. 17, 20 cases, 12 deaths; Oct. 31, still present.
Venezuela: Caracas, Oct. 7, 1 case.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

CHOLESTERIN IN PERNICIOUS ANEMIA.

LEAVENWORTH, KAN., Nov. 30, 1908.

To the Editor:—In an editorial, November 21, THE JOURNAL mentioned the use of cholesterin in the treatment of pernicious anemia. I am much interested but am unable to obtain the cholesterin and should like to know of a process by which I might be able to obtain the same from the bile.

CHARLES J. MCGEE, M.D.

ANSWER.—The most common source of cholesterin is cholesterin gallstones. The following is one method of obtaining it. The concretions are finely pulverized and extracted with boiling water and then with boiling alcohol. From the alcoholic extract the cholesterin crystallizes out on cooling and is then boiled with an alcoholic solution of sodium hydroxid so as to saponify the fats which are present. The alcohol is distilled off and the residue extracted with ether, which removes the cholesterin and leaves the soaps behind. The ether is separated and evaporated, leaving the cholesterin in a crystalline form. It can be further purified by recrystallization from a mixture of alcohol and ether (Simons: Physiological Chemistry).

While we find no specific method for preparation from the bile, it is probable that it might be obtained by evaporating the liquid to dryness, extracting with ether and treating the ethereal residue as above described. We believe, however, that the manufacture would present such difficulties as to make it impracticable for the physician or pharmacist, unless he had the facilities of a manufac turing chemist. The present price of cholesterin is about 50 cents per gram, but the price will doubtless be greatly reduced as soon as there is a sufficient demand. Cholesterin crystallizes in characteristic colorless, transparent plates, with ragged margins and angles. The crystals melt at 145 C. (293 F.). It is nearly insoluble in water, dilute acids and alkalies, but dissolves with ease in ether, chloroform, benzol, and in boiling alcohol. From its ethereal solution it crystallizes out in the form of fine needles. It is also soluble in the essential and fatty oils and is held in solution in the bile by the presence of the bile salts.

EFFECT OF CHLORIN WATER ON CALOMEL.

Davis, W. Va., Dec. 7, 1908.

To the Editor:—In The Journal, *November 28, I note an inquiry* as to the effect of giving chlorin water and calomel at the same time. I have given many hundred doses of calomel to patients who were taking chlorin water at the same time and none of these patients ever showed any signs of mercurial poisoning.

A. P. Butt, M.D.

Answer.—There is no doubt that chlorin water acting on calomel will convert it into corrosive sublimate. If the chlorin water and calomel were mixed before taking there would be great danger that all the calomel would be converted into the poisonous corrosive sublimate and serious symptoms or fatal poisoning result. The mixture is an incompatible one which should be most scrupulously avoided. In case the calomel is given at a separate time, the effect will depend on the amount of chlorin water in the stomach at the time the calomel is taken and on the dose of the calomel. In this case also care should be exercised, since it is quite possible that chlorin water may have remained in the stomach beyond the time when one would expect it to have passed into the intestine. It is wise to bear in mind the fact that some patients are very susceptible to poisoning by mercury. In explanation of the fact that our correspondent has not seen bad effects from this practice, it should be noted that when chlorin comes in contact with food or liquids containing much organic matter it is reduced and no longer acts on calomel.

INROADS OF WORMS ON FAMILY PRACTICE.

To the Editor:—The following experience has occurred repeatedly in my neighborhood: A child is ailing and the grandmother at once says, "Worms." The family physician smiles at the old lady's diagnosis and prescribes tonics, etc., after frightening the family by asking for specimens of his little patient's sputum and urine. He never asks for specimens of the stool. As the child continues ailing and peevish, the mother yields to the old lady's insistence and gives some patent worm tablets, without the doctor's knowledge, but with the result that the child passes a pint of worms. The confidence of that family in medical science is shaken, and henceforth "grandmother's remedies" reign supreme. "Doctors nowadays have got beyond worms, but we grandmothers know better." When the home remedies fail, the family is ripe for Eddyism. Layman.

Answer.—The suggestion that a child's indisposition may be due to worms is so frequently made that it would be strange if it did not prove to be true once in a very great while. Although the circumstances narrated are rare, it is well to bear in mind that the grandmother may be right.

Medical Education and State Boards of Registration

COMING EXAMINATIONS.

Arizona: Phoenix, Jan. 4-5. Sec., Dr. Ancil Martin.

Arkansas: Little Rock, Jan. 12. Secretaries: Regular, Dr. F. T. Murphy, Brinkley; Homeopathic, Dr. P. C. Williams, Texarkana; Eclectic, Dr. A. J. Widener, Little Rock.

Colorado: Denver, Jan. 5. Sec., Dr. S. D. VanMeter, 1723 Tremont St.

District of Columbia: *Washington, Jan. 12. Sec., Dr. George C.* Ober, 210 B. St., S. E.

Illinois: Coliseum Annex, Chicago, Jan. 18-20. Sec., Dr. J. A. Egan, Springfield.

Minnesota: Old Capitol, St. Paul, Jan. 5. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg.

New Hampshire: Concord, Dec. 29-30. Regent, Mr. H. C. Morrison.

New Mexico: *Santa Fe, Jan. 11.* Sec., Dr. J. A. Massie.

South Dakota: Sioux Falls, Jan. 13-14. Sec., Dr. H. E. McNutt, Aberdeen.

Utah: Salt Lake City, Jan. 2 Sec., *Dr. R. W. Fisher.*

Vermont: Montpelier, Jan. 12-14. Sec., Dr. W. Scott Nay, Underhill.

Washington: Spokane, Jan. 5-7. Sec., Dr. Kenneth Turner, Walker Bldg., Seattle.

Wisconsin: Milwaukee, Jan. 12-14. Sec., Dr. J. V. Stevens, Jefferson.

Marriages

W. L. Marshall, M.D., Viola, Ala., to Miss Eula Seymour, of Roanoke, Ala., recently.

John E. Gleason, M.D., to Miss Eleanor Merrill Hovey, both of Detroit, November 24.

Richard S. Benner, M.D., to Miss Marion McClean, both of Springfield, Mass., November 18.

Edward H. Egbert, M.D., to Miss Elizabeth Hawes, both of Washington, D. C., November 26.

John A. Williams, M.D., to Mrs. Susan Reece Hume, both of Greensboro, N. C., December 3.

J. King B. E. Seegar, M.D., Baltimore, to Miss Elizabeth Bosley, at Towson, Md., December 2.

Arett C. Arnett, M.D., Lafayette, Ind., to Miss Ethel McKinstray, of Noblesville, Ind., recently.

Chester M. Counsell, M.D., Kansas City, Mo., to Miss Ruth Truitt, of Dyersville, Iowa, December 1.

William E. Gossett, M.D., Buffalo, Wyo., to Miss Laura M. McKown, of Sheridan, Wyo., November 22.

Ashby M. Taylor, M.D., Elsberry, Mo., to Mrs. Mary J. Cornick, of Batchtown, Ill., September 24.

Harry Field Parker, M.D., Warrensburg, Mo., to Miss Martha Sousley, of Lowville, N. Y., November 25.

Alfred Turpin Calhoun, M.D., Cartersville, Ga., to Miss Emma Thornton, of Talladega, Ala., November 18.

Reid Hunt, M.D., U. S. P. H. and M.-H. Service, to Miss Mary Lillie Taylor, of Washington, D. C., December 12.

Deaths

William Whitfield Miller, M.D. University of Virginia, Charlottesville, 1901; afterwards assistant in bacteriology in Columbia University; assistant pathologist and for two years a member of resident staff of the Roosevelt Hospital, demonstrator of pathology at the College of Physicians and Surgeons, Memphis, in 1905; commissioned as assistant surgeon in the U. S. P. H. and M.-H. Service in 1906; and a year later assigned to the Hygienic Laboratory of the Service in Washington; who had made especial investigation of the origin and prevalence of typhoid fever and did much original work in the search for bacillus carriers; who discovered a pathogenic hemogregarine in the blood of white rats, described its life cycle and the mechanism of infection by the digestive tract, a preliminary note of which was published in the Public Health Reports, July 24, the completed work forming Hygienic Laboratory Bulletin No. 46; died in *Providence* Hospital, Washington, November 24, from typhoid fever, aged 28.

John Thorne Wheeler, M.D. Bellevue Hospital Medical College, New York City, 1876; a member of the American Medical Association; formerly vice-president of the Medical Society of the State of New York and president of the Columbia County Medical Society; who inaugurated the Third District Branch of the Medical Society of the State of New York and was its vice-president; medical expert to, and director of, the division of communicable diseases of the State Department of Health; local surgeon at *Chatham*, N. Y., for the New York Central Lines, and the Rutland Railway; a member of the local board of education for twenty-seven years; died at his home, December 3, from pneumonia, aged 57.

Joseph Dobbins Davidson, M.D. Vanderbilt University, Nashville, 1882; a member of the American Medical Association; president of the Burnett Sanitarium, Fresno; formerly health officer of Fresno county; and a prominent surgeon; died at his home November 30, from heart disease, aged 46. The Fresno County Medical Society, at its meeting December 1, appointed a committee to prepare resolutions relative to Dr. Davidson's death, and then adjourned as a mark of respect to his memory.

Bethuel Lewis Dodd, M.D. College of Physicians and Surgeons, New York City, 1852; for twenty-five years a practitioner of Newark, N. J., for a time police surgeon for the city, and surgeon-in-chief for the Pennsylvania Railroad, and physician of Essex county; examining surgeon for the Thirteenth and Twenty-Sixth New Jersey Volunteer Infantry during the Civil War; died at the home of his son in Newark, *December 7,* from senile debility, aged 83.

George H. Bicknell, M.D. University of Nebraska, Omaha, 1895; a member of the American Medical Association; adjunct professor of ophthalmology in his alma mater; rhinologist and laryngologist to the Clarkson and Nebraska Methodist hospitals, Omaha; a well-known oculist and aurist; died in the Methodist Hospital, Omaha, November 28, from septic pneumonia, following an abdominal abscess of several months' standing, aged 44.

Joseph Maurice Fox, M.D. Jefferson Medical College, Philadelphia, 1852; a Confederate veteran; originally a practitioner of Sedalia, Mo., but later a member of the World's Fair Commission from Montana; general superintendent of the Oregon Railway and Navigation Company; and general manager of the Northern Pacific coal properties; died at the home of his daughter in Victor, Colo., November 28, from cerebral hemorrhage, aged 76.

Mary L. Craffey-Osgood, M.D. New England Female Medical College, Boston, 1865; for thirty-five years a practitioner of St. Louis; who did heroic work in Memphis, Tenn., during the yellow fever epidemics in 1878 and 1879, where she was in charge of one of the emergency hospitals; died at her home, December 3, from heart disease, aged 60.

Franz Muecke, M.D. University of Griefswald, Germany, 1856; surgeon of the Fifty-Eighth New York Volunteer Infantry, during the Civil War; who later filled several governmental positions in Germany, and afterward returned to this country, settling at Rochester, N. Y.; died at his home in that city, November 26, aged 75.

Ella A. Jennings, M.D. New York Medical College and Hospital for Women, New York City, 1878; founder of two Providence Dispensaries for women and children in Brooklyn; and for many years editor of *Humanity and Life;* died in King's County Hospital, Brooklyn, November 29, aged 59.

Calhoun Sams, M.D. Medical College of the State of South Carolina, Charleston, 1860; assistant surgeon and later surgeon of Colonel Black's South Carolina Cavalry in the Confederate service during the Civil War; died at his home in Taylor, Texas, November 22, aged 70.

Charles William Murset, M.D. Cornell University, New York City, 1905; of West New Brighton, Borough of Richmond, N. Y.; house physician at St. Vincent Hospital and the Seton Hospital, Staten Island; died at the home of his aunt in Meriden, Conn., November 28.

Edith A. Root, M.D. Northwestern University Womans' Medical School, Chicago, 1875; a pioneer practitioner of Denver, Colo.; and some-time president of the Denver Clinical Club; died at her summer home in DeKalb, Ill., from pneumonia, November 26, aged 67.

John Armstrong Lindsay, M.D. Western Reserve University, Cleveland, 1856; a member of the American Medical Association, and one of the oldest practitioners of Columbiana county, Ohio; died at his home in Salineville, December 3, from cerebral hemorrhage, aged 75.

Percy Lothrop, M.D. Long Island College Hospital, Brooklyn, 1901; a member of the Samoset Medical Society of Plymouth, Mass.; physician and surgeon to Jordan Hospital; died suddenly at his home in Plymouth, November 20, from heart disease, aged 31.

William J. Earhart, M.D. Homeopathic Medical College of Pennsylvania, Philadelphia, 1864; one of the founders and for several years in charge of the Hahnemann Hospital in that city; was found dead at his home December 4, from heart disease, aged 67.

J. Nathaniel Henry Huggins, M.D. Rush Medical College, Chicago, 1880; a member of the State Medical Association of Texas; and a Confederate veteran; for several years city physician of Georgetown; died at his home November 29, aged 76.

John P. Houston, M.D. Chattanooga (Tenn.) Medical College, 1904; a member of the Medical Association of the State of Alabama; died at his home in Arbacoochee, near Heflin, Ala., December 5, from injuries received by being struck by a train.

Cullen M. Cottongim, M.D. Memphis Hospital Medical College, 1906; of Teague, Tenn.; a member of the Tennessee State Medical Association; was shot and killed as the result of a feud, December 6, aged 37.

Albert B. Pitts, M.D. Washington University, St. Louis, 1882; Tulane University, New Orleans, 1883; was shot and killed in his office in Hazelhurst, Miss., December 10, by a professional rival.

Emery M. Henry, M.D. Southern Homeopathic Medical College, Baltimore, 1892; of Laurel Point, W. Va.; died in the Maryland Homeopathic Hospital, Baltimore, December 2, aged 40.

Solomon S. Carr, M.D. American Medical College (Eclectic), St. Louis, 1882; a member of the first school board of Ardmore, Okla.; died at his home in that city, December 1, aged 76.

Daniel Webster Styer, M.D. Jefferson Medical College, Philadelphia, 1888; a member of the American Medical Association; died at his home in Churchtown, Pa., December 7, aged 45.

John C. Ireland, M.D. Miami Medical College, Cincinnati, 1908; an interne at the German Deaconess Hospital, Cincinnati; died in that institution, November 28, from typhoid fever.

John A. Rega, M.D. University of Heidelberg, Germany, 1848; was fatally burned by the explosion of a gasoline stove in his home in Gouverneur, N. Y., November 29, aged 87.

John W. Acuff (License, Tenn., 1889) for more than forty years a practitioner of Tennessee; died from cerebral hemorrhage at his home in Bellbuckle, November 30.

Louis Philip Knapp, M.D. College of Physicians and Surgeons, New York City, 1891; died at his home in Hackensack, N. J., from liver disease, December 3, aged 39.

Dennis J. Boudreau, M.D. Saginaw Valley Medical College, Saginaw, Mich., 1903; of Newberry, Mich.; died in that place November 19, from typhoid fever, aged 33.

Norval Smith, M.D. Queen's University, Kingston, Ont., 1904; of Bridgeport, Conn.; died in the Bridgeport Hospital, December 1, from cerebrospinal meningitis.

George C. Richards, M.D. University of Nashville, 1868; a Confederate veteran; died at his home in Nashville, December 4, from cerebral hemorrhage, aged 74.

Luther L. Chamblin, M.D. College of Physicians and Surgeons, Baltimore, 1878; died at his home near Philomont, Va., December 2, from paralysis, aged 53.

William Emrich Walker, M.D. Harvard Medical School, Boston, 1902; died at his home in Fairhaven, Mass., November 30, from pleuropneumonia, aged 34.

Jay H. Fordyce, M.D. Medical College of Ohio, Cincinnati, 1879; of Wichita, Kan.; died in the Wichita Hospital, December 3, from heart disease, aged 54.

William Henry Winter, M.D. University of Nashville (Tenn.), 1902; died at his home near Hickman, Ky., November 20, from pneumonia, aged 43.

Frederick W. H. Herbertz (years of practice, Mich., 1900), for thirty years a practitioner of Detroit; died at his home, December 7, from dropsy, aged 62.

Frederick N. Burgess, M.D. Harvard Medical School, Boston, 1865; a veteran of the Civil War; died at his home in Hantsport, N. S., recently, aged 66.

Charles R. Keyes, M.D. Detroit (Mich.) Medical College, 1875; died at his home in Ludlowville, N. Y., December 1, from nephritis, aged 58.

Thomas C. Tipton, M.D. Starling Medical College, Columbus, Ohio, 1852; died at his home in Williamsport, Ohio, November 27, aged 80.

Nelson S. Darling, M.D. Starling Medical College, Columbus, Ohio, 1853; of Laporte, Ind.; died in Wichita, Kan., December 10, aged 77.

Joseph W. Kelly, M.D. Rush Medical College, Chicago, 1894; died at his home in Hudson, Wis., December 2, from pneumonia, aged 38.

Nathaniel L. Story (License, Iowa, 1886); for thirty years a practitioner of Iowa; died at his home in Mitchell, November 19, aged 64.

John Homer, M.D. Harvard Medical School, Boston, 1865; of Newburyport, Mass.; died at his home, November 24, aged 73.

M. D. Alford, M.D. Vanderbilt University, Nashville, 1883; of Roberson Fork, Tenn.; died at his home, November 22, aged 56.

George H. Voss, M.D. Hahnemann Medical College, Chicago, 1899; died at his home in Detroit, December 5, aged 41.

John H. Schriefer, M.D. University of Louisville, 1891; died at his home in Prospero, Ind., November 20, aged 47.

Book Notices

ATLAS OF CLINICAL SURGERY, with Special Reference to Diagnosis and Treatment. By Dr. Ph. Bockenheimer, Professor of Surgery in the University of Berlin. English Adaptation by C. F. Marshall, M.D., F.R.C.S., Late Assistant Surgeon to the Hospital for Diseases of the Skin, London. Three Volumes. Flexible Leather, with illustrations. Price, $24.00 per set. New York: Rebman Co.

The nature, scope and aim of this work is indicated by the following extract from the author's preface: "Those who are acquainted with the history of medicine know that, even in ancient times, it was sought to represent pictures of disease by the aid of plastic art. No wonder, then, that, at the present day, when medicine has made such great progress in all domains, we take advantage of all measures which may facilitate the study of morbid conditions. The rich material of von Bergmann's clinic, which has been placed at my disposal, renders it possible to give plastic representations of all surgical diseases which are suitable for production in this way. The models were executed with greatest skill by F. Kolbow in the pathoplastic institute at Berlin, and have proved of much value in the teaching of clinical surgery. The models have been reproduced by the four-color process, which gives a more natural appearance than can be obtained in reproduction with water colors. In this work clinical pictures have been represented with a view to assist the practitioner in diagnosis and to give the student a survey of the more important surgical diseases. For this purpose, the malignant and benign tumors, a number of pyogenic, tuberculous and syphilitic conditions which are common in surgical practice, have been figured and described, along with numerous other cases which belong to the domain of surgery."

The tendency in anatomy of late has been to employ atlases presenting thus a clear picture of structures and their relations. The atlases of anatomy written by Spalteholz and Toldt, have proved eminently satisfactory to teachers in presenting the subject to students. Bockenheimer has employed this method in his clinical atlas, presenting a picture of a typical lesion, to which is appended a short description of the clinical course of the disease, differential diagnosis, prognosis and treatment. The book bears the same relation to the subject of clinical surgery that the atlas of Spalteholz does to that of gross anatomy. The four-color process reproduces faithfully the lesions in their original colors. The descriptions are short, but clear. Their value is increased by the fact that in most cases the experience of but a single authority is given. The translation, although somewhat literal, is very readable. The book is destined to occupy the same place in clinical surgery that the atlases prepared by Spalteholz and Toldt do in anatomy.

DIE KOMPLIKATIONEN DER STIRNHÖHLENENTZÜNDUNGEN. Von P. H. Gerber, a.o. Professor und Direktor der Königl. Universitäts-Poliklinik fur Hals und Nasenkranke in Königsberg i. Pr. Paper. Pp. 457, with illustrations. Price, $3.60. Berlin: Verlag von S. Karger, 1909.

This book contains an exhaustive critical study of all that is known regarding those complications of inflammation in the frontal sinus which call for operative interference. It includes a study of the normal anatomy and histology of the frontal sinus, the methods of infection, the bacteriology and a detailed study of the various pathologic changes in the membranes and walls of this sinus. The latter is treated under the following subheadings: "Periostitis and Ostitis," "Antritis Frontalis Abscedens," "Antritis Frontalis Dilatans," "Pneumatocele," "Cholesteatoma" and "Osteomyelitis." Under "Organ Complications" are discussed the oculo-orbital complications and the intracranial complications. The concluding chapters contain a general discussion of etiology and therapy.

TEXT-BOOK OF HUMAN PHYSIOLOGY. By George V. N. Dearborn, A.M., (Harv.) Ph. D., M.D. (Col.), Professor of Physiology in the Medical and Dental Schools of Tufts College, Boston. Cloth. Pp. 550, with illustrations. Price, $4.00. Philadelphia: Lea & Febiger. 1908.

In this book we have an attempt to present the important facts of physiology in sufficient detail for the needs of students of medicine and dentistry without going to the extreme length so noticeable in a number of works used in the medical schools of this country. Dr. Dearborn appears to possess a proper sense of proportion, and has avoided padding his book by the introduction of matter of secondary importance only and by quoting a long aray of literature references, which for the freshman or sophomore are often worse than useless, since they frequently confuse, rather than assist. A text-book for beginners in medicine need not be a complete reference manual. The book is divided into thirteen chapters, treating of the topics usually included in works on general physiology. These chapters are well illustrated, a fair proportion of the illustrations being apparently new. Chapter 12 is devoted to a discussion of mental processes and the relations of mind and body. The extent of this discussion is somewhat unusual in a text-book of this character, but it can not be said to be out of place. In a lengthy appendix full directions are given for performing a large number of important illustrative experiments, so that in a sense the book is likewise a laboratory manual.

In the main the style and treatment are satisfactory, and what Dr. Dearborn has to say is presented in a tangible and straightforward manner, which in a text for beginners is always of the first importance. But, unfortunately in his efforts at simple elucidation he has frequently sacrificed accuracy. An illustration of this is found in the color plate facing the title-page, which is described as a diagram of cell metabolism. Such a sketch as a blackboard illustration, with proper explanation of its tentative character and limitations, might be very helpful, but as presented it conveys a wrong impression as to the extent of our knowledge on several points. The same general objection may be urged against the diagram on page 27. While this is described as "highly diagrammatic," it must still be urged that the impression it would convey to the average student would be an erroneous one. There are also a number of illustrations which seem to have but little relation to matters presented in the text. The specialist in histology, embryology or chemistry will be able to pick out a number of departures from strict accuracy in the discussions, but most of these appear to be of minor importance, and may be, perhaps, overlooked in a first edition. On the whole the book should find a place in the instruction of medical students.

WALSH'S PHYSICIAN'S COMBINED CALL-BOOK AND TABLET, Monthly Form. Thirtieth Edition. Flexible Leather, with Pocket and Special Memoranda. Price, $1.50. Washington, D. C.: Ralph Walsh, M.D.

WALSH'S PHYSICIAN'S HANDY LEDGER. A companion to "Walsh's Physician's Combined Call-book and Tablet." Cloth. Pp. 600 (for 600 patients). Price, $3.50. Washington, D. C.: Ralph Walsh, M.D.

THE MEDICAL RECORD VISITING LIST for 1909. Flexible Leather, with pocket and special memoranda. New Revised Edition. Price, $1.50. New York: William Wood & Company.

THE PRACTITIONERS' VISITING LIST for 1909. Flexible Leather, with flap, pocket and pencil, calendar for two years, and dose list and other memoranda. Price, $1.25. Philadelphia: Lea & Febiger.

The three visiting lists are all handy, compact, durable and well made, and will prove of great labor-saving value to the practitioner. The Medical Record and the Practitioner's books are issued in various forms, according to the size of the practice and the preference of the user. As to data included, all are about alike. The data are most valuable for the physician to have with him at all times. The Walsh call-book is arranged for the record of a patient through a whole month without rewriting the name. It is intended to be used in connection with the ledger in which a page is given to each patient, the two books being intended to be used in combination at a minimum expense of time and yet with the advantage of being able to see without difficulty the charges and the nature of the various items of attendance for the whole year.

PAIN, Its Causation and Diagnos [illegible] in Internal Diseases. By Dr. Rudolph Schmidt, [illegible] Hof-rat von Neusser, Vienna. Trans [illegible] M. [illegible] and Vogel, M.D., Instructor in Pathol [illegible] M.D., Surgeons, Columbia University, a [illegible] Instructor in Bacteriology. College of Physicians and Surgeons, Columbia University. Cloth. Pp. 326, with illustrations. Price, $3.00. Philadelphia: J. B. Lippincott Co.

This book deals with the diagnosis of visceral diseases, starting with the symptomatic pain which may accompany them. The discussion of pain, its quality, its location, its cause and its significance in individual diseases is preceded by chapters on "The Sensation of Pain," "Functional Modifications of Pain," "Topography in Its Relation to Pain," and "Quality and Times of Occurrence." About 30 pages are devoted to the nervous system, a brief chapter to organs of motion, about 120 pages to diseases of the digestive system, including the liver and pancreas, about 30 to the urinary system and spleen, and finally a brief chapter to the respiratory and circulatory systems. The pages which treat of the digestive system are the most satisfactory for the diagnosis of painful diseases of this system is considered very fully.

The details of Schmidt's views can not be gone into in this review, but to give the reader an idea of his style and opinions on one subject, the following is selected from the 20 pages devoted to pain in round ulcer of the stomach, in which he considers fully the diagnosis of the disease. Correctly, as we believe, Schmidt lays more stress on hyperchlorhydria than most do. He says: "I consider hydrochloric hyperacidity is very far from frequent in ulcer and have, furthermore, been able to convince myself that in undoubted cases of the lesion even large doses of dilute hydrochloric acid have not increased the pain. There may exist what I think is rather frequent, namely, a hyperesthesia to hydrochloric acid accompanied by even subnormal hydrochloric acid values." Much weight is attached to the stretching of the stomach walls by flatus as cause of pain in ulcer. The whole subject, however, is most interestingly considered.

Schmidt attaches only moderate diagnostic value to the time after eating when pain appears. It may occur quickly after eating in pyloric ulcer or be much delayed. He does attach importance to the promptness with which it can be relieved by anesthesia or cocain. If the ulcer is in the stomach or esophagus, pain disappears in about fifteen minutes after the drug is administered.

Students of diagnosis will find this book invaluable, and will appreciate Schmidt's accuracy, fulness of statement and good judgment. The book is well translated; the few lapses from idiomatic English are negligible.

SURGICAL MEMOIRS AND OTHER ESSAYS. By James G. Mumford, M.D., Instructor in Surgery, Harvard Medical School. Cloth. Pp. 358, with Illustrations. Price, $2.50. New York: Moffat, Yard & Co., 1908.

This is a group of addresses and papers, some already published individually in different journals and books, as well as others not heretofore printed. The introductory chapter is a historical review of surgery, and appeared as the first chapter of Keen's "Surgery." This narrative of surgery includes brief sketches of some of the historical characters in medicine, of those who have made American surgery, and a more extended account of Lord Lister and his work. "Teachings of the Old Surgeons" is an interesting chapter, critically reviewing the work and views of the surgeons of old. It shows that there was some good philosophy and not a little sound reasoning in the surgical literature of the past, and that good judgment was used in much of the work of the old surgeons. Sketches of Sir Astley Cooper, John Collins Warren and Jacob Bigelow occupy chapters. In an address, "Boston Medicine One Hundred Years Ago," is a delightful sketch of that remarkable, but little known character, little known, that is, as a medical man, Dr. Samuel Gridley Howe, to whom the blind and feeble-minded owe so much. "Studies in Aneurism" is a historical account of this condition and the methods of its cure, leading up to and including a description of the brilliant yet simple method originated by Matas of New Orleans. "Present Problems" and "The Nurse's Vocation" are addresses to nurses. The volume closes with a short chapter on "History and Ethics in Medicine."

These essays are all delightful and interesting; but more important, they are instructive and stimulating to good work.

A TEXT-BOOK OF DISEASES OF WOMEN. By Charles B. Penrose, M.D., Ph.D., Formerly Professor of Gynecology in the University of Pennsylvania. Cloth. Sixth Edition. Pp. 550, with illustrations. Price, $3.75. Philadelphia: W. B. Saunders Co., 1908.

This volume, originally written with particular regard for the demands of the medical student, remains in this respect unchanged. The subject matter is compactly and concisely presented, and the price is attractive to the average undergraduate. In general it may be said that the reader is not confused by abstract theorizing or by a complex presentation of the various subjects discussed. Only one plan of treatment for each disease is considered, and only such facts relating to anatomy, physiology and pathology are mentioned in any detail as seem necessary for the elucidation of the point being made. The arrangement of the subject matter has not been changed. Thus Penrose takes up in detail the treatment of his operative procedures subsequently to his consideration of the various surgical diseases. This is, again, a distinct advantage. The various neoplasms are treated in an adequate manner and the plastic work is described according to the methods employed by the best teachers.

Miscellany

Professor Martin's Impressions of America.—Our Berlin correspondent has recently described in detail (THE JOURNAL, October 10, page 1246, and October 31, page 1523) the manner of organization of the profession in Germany in compulsory "public" medical councils and in "private" associations. Prof. A. Martin and Prof. A. E. von Rosthorn, the editors of the *Monatsschrift für Geburtshülfe und Gynakologie*, have been guests of the American Medical Association at annual sessions. Professor Martin, in an editorial in the October number of his journal, pays a high tribute to the scientific and other aspects of the Chicago session, remarking in conclusion: "The American Medical Association represents in an extremely powerful form our various organizations for scientific and economic purposes. In its organization it forms a mighty force which issued from the private initiative of the physicians of the United States, and is working with insight and power to raise the medical profession in every direction. It was a delight to see our colleagues at work also in this line. This organization is certainly not the least factor in the vast medical and educational development of the last twenty-one years which I had ample opportunity to observe during my trip across the continent to the Pacific coast." He commends the rules of membership in the American Gynecological Society, whose annual meeting he also attended, and comments on the management of the medical colleges, remarking that the faculties in American colleges are not composed, as in Germany, each of one or two regular and one or two assistant professors and privat docents, but of a very large teaching force. The professors not only divide among themselves the theoretical and practical instruction but also change frequently in the charge of the hospital services. He has been able to watch this great development along all lines during the twenty-one years since he has been coming to this country, but states that the specialty of obstetrics has only a few representatives. "Instruction in obstetrics is not given even approximately as in Germany, except at a very few points. I believe that only Philadelphia, Baltimore, Chicago and New York have large maternity hospitals connected with the medical colleges. Generally there are only a few beds for the lying-in department. Instruction is almost exclusively theoretical; practical instruction is offered in the polyclinics, with which a few prominent instructors are connected and where they work with commendable zeal. There is an absolute lack of pregnant women as teaching material except where there are Slavic and oriental immigrants. 'Gynecology' seems to mean in the United States merely 'abdominal surgery.' Only a few of the prominent gynecologists pay any attention to the so called minor gynecology, but all seem to regard operations on the appendix, gall bladder and kidneys as pertaining to their domain. This explains the exclusive choice of abdominal section in preference to vaginal operations. Under these conditions it was noticeable that several of the papers at the meeting were devoted to obstetrics or kindred subjects." Martin remarks further that manikins for teaching purposes do not seem to be much known, "probably because of the difficulty of obtaining the cadaver models." He deplores further the prevailing lack of training in vaginal operations, ascribing the neglect of the vaginal route in large measure to the custom of removing the appendix when the abdominal cavity is entered for any reason.

Coliuria and Colitoxemia.—Under these names, F. Kornfeld (*Beiblatt z. d. Mitt. d. Gesellsch. f. inn. Med. u. Kinderh. in Wien*, 1908, vii, No. 5) calls attention to a subject the importance of which had not been fully appreciated prior to his earlier articles published in 1904 and 1906, viz., the exclusive infection of the bladder by the colon bacillus and the symptoms it produces. The freshly evacuated urine, in the cases here considered, is uniformly turbid from the included colon bacilli, other species not being present; and the condition is to be sharply distinguished from the bladder inflammation caused by mixed infection. It is a much less frequent disorder, is certainly not a preliminary stage, and is not associated with or followed by a pyelitis or cystopyelitis Its characteristic features—the immense amount of bacteria, the constant acid reaction of the urine, which lasts for a long period in exposed vessels after evacuation, and the peculiar stale, carrion-like, but never ammoniacal odor are all different from those of any other condition. Inoculations on animals sometimes fail of effect, sometimes cause local abscess, and in rare cases may cause fatal embolism. In all cases an increased turbidity follows milking of the prostate gland, but the colon cultures remain the same. The duration is long, even two decades or more; the origin of the bladder infection is considered to be mainly from the bowel through the intervening tissue or by way of the lymphatics. Another characteristic feature is the sudden febrile attacks which occur in many of the cases, resembling the inception of an acute infectious disorder, with chills, high temperature, prostration, anorexia, vomiting, etc., which, nevertheless, entirely subside in twelve or twenty-four hours, leaving the patient temporarily somewhat prostrated but otherwise soon in his usual health. These, Kornfeld considers, must be recognized as a special colitoxemia. Kornfeld here excludes from consideration a form of hematogenous colon bacillus infection, which frequently has the kidney pelvis as its point of entrance, and which also begins with symptoms suggesting septicemia; in his article he takes account of the coliuria only in the limited sense above described.

Heberden's Nodes.—L. Wick (*Beiblatt z. d. Mitt. d. Gesellsch. f. inn. Med. u. Kinderh. in Wien*, 1908, vii, No. 5) in a rather elaborate paper sums up his conclusions as to the nature, etiology, etc., of these growths as follows: Heberden's nodes are the expression of a trophic disturbance, a degeneration, which develops on the basis of a definite predisposition as an essential condition. As far as now known, the components of this predisposition are, senescence, a neuropathologic tendency (Anlage), but before all others, the decrease or disappearance of the function of the sexual glands; this last is in many instances perhaps the only determinable factor. There may be, he admits, other contributing conditions, among which are chronic rheumatism and gout, but it need not be identified with them. The nearest relations of the condition seem to be with arthritis deformans, but Wick is not inclined to consider it a phase of that disorder. The trophic skin changes and the sensory or vasomotor disturbances, point to the nervous system as participating largely in the disturbance. As regards treatment, he does not express himself very hopefully. He has never seen a spontaneous cure. The use of organotherapy would naturally be suggested with his view of the etiology and it has been experimented with by Badt, but apparently without marked results. Its value would be most probable in the incipiency of the condition. Von Noorden has reported good results from the use of hot hand baths and electricity and suggests the Bier hyperemia treatment as sometimes worth trying. The predisposing causes, gout, rheumatism, etc., are of course to be attended to as far as possible.

Influence of Temperature on Calf Vaccine.—A. B. Green, in the *Journal of Hygiene*, discusses this subject in detail and concludes that: (1) Temperature influences the rate at which glycerinated lymph deteriorates in accordance with the law of Arrhenius, expressing the effect of temperature on chemical action; the rate of deterioration increasing three times per 10 degrees rise in temperature. (2) Dry powdered calf vaccine in sealed glass capillary tubes still gave rise to typical vesicles after exposure to a temperature of 100° C. for from 5 to 10 minutes. (3) The vaccine virus can withstand positive osmosis for 24 hours or more, and negative osmosis for 8 weeks or more, at room temperature. (4) It appears doubtful whether the vaccine virus will pass through a Berkefeld V filter even when a stored vaccine emulsion is used for filtration. If any virus does pass through, it only does so exceptionally and in small quantities. (5) When a glycerinated vaccine emulsion is filtered, white flocculi frequently form in the filtrate. These are at first minute, but subsequently adhere and form a macroscopic sediment. This sediment, when inoculated on calves, does not cause vesiculation. Microscopically these flocculi, in hanging drop preparations, resemble the vaccine bodies described by one or more observers.

Sanitation in Africa.—It is claimed that for a West African town, Bathurst, the capital of Gambia, may be said to be very presentable The streets are wide and clean, and mosquito and sanitary regulations are properly enforced, while a new departure has been made in putting representatives of the Mandingos and Joloffs on the Board of Health, apparently with satisfactory results. There were several outbreaks of smallpox in the colony during the last year; over 4,700 persons were vaccinated, and the natives, who at first refused to allow their children to be vaccinated, soon recognized its utility and sought to have it done. An attempt is being made to get a rough idea of the vital statistics of the people, and the chiefs were given red and blue books and instructed to mark in them all births and deaths in their district. Although these statistics are probably not too accurate, they will doubtless improve. The Bathurst death rate is only 31.6 per mille; but the climate is very trying during the rainy season from July to October, and in the dry season the thermometer may range from 56 F. in the early morning to 100 at midday.—*British Medical Journal.*

Society Proceedings

COMING MEETINGS.

American Assn. of Anatomists, Baltimore, Dec. 29-31.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Oct. 28, 1908.

The President, Dr. Albert M. Eaton, in the Chair.

SYMPOSIUM ON TYPHOID FEVER VARIATIONS.

Abdominal Complications of Typhoid from a Surgical Standpoint.

Dr. Francis D. Patterson: The importance of the subject is best indicated by its frequency as shown by statistics. Vaughan states that the frequency of perforation has been variously estimated from 1.3 to 11 per cent. I have collected from literature a total of 21,215 cases of typhoid in which 671 perforations occurred, a frequency of 3.16 per cent. Figures of the Census Bureau show the average mortality from typhoid fever during the years 1901 to 1905 inclusive in the registration area to be 10,458 deaths per year. In 1906 this was increased to 13,160 deaths, these figures being exceeded only by those of six other countries. Pennsylvania contributed 3,917 deaths from the disease in 1906, and in Philadelphia from Jan. 1, 1903, to Sept. 15, 1908, there were 32,218 cases of typhoid fever, with 4,930 deaths. One death in every every three was due to perforation, which would give 1,613 perforative cases in Philadelphia alone during that time. Statistics show that perforation is as frequent in children as in adults; the existing causes are as a rule mechanical. Case reports show that perforation may occur during any period of the disease and in convalescence, but is most common between the second and fifth week inclusive. While in the majority of cases the lesion is found in the ileum, no portions of the intestinal tract are exempt. The lesions in typhoid are usually on the free border of the intestine opposite to the mesenteric attachment. The blood supply here being relatively poor, there is a predisposition to necrosis and perforation. When this takes place it is usually into the free peritoneal cavity and not between the folds of the mesentery. The symptoms should be divided into those occurring at the time of perforation, and those of the succeeding peritonitis. There is no pathognomonic sign of perforation. An accurate diagnosis is difficult in many cases. The prognosis of every case of perforation depends on the celerity with which operation is performed and the bacteriology of the resulting peritonitis. The streptococcic infections are usually fatal, while the chances of recovery are good in those due to the colon bacillus [The technic of the operation was described in detail and the report made of 842 cases with 609 deaths, a mortality of 72.32 per cent., which included the 362 cases reported by Harte and Ashhurst in their classical papers.] There is need of a close cooperation between physicians and surgeons in the management of cases of typhoid fever. The literature shows that typhoid fever patients stand operative interference better than would be expected.

Viability of the Typhoid Bacillus in the Body.

Dr. Norman B. Gwyn: Two phases may be recognized: 1, the period of the primary infection and convalescence—about six months; 2, the period of post-typhoid lesions or bacillary persistence—possibly the remainder of the patient's life. In the first period the viability is really more of a luxurious proliferation, the bacilli being readily found in the blood and almost every part of the body, giving rise to infections of various organs and parts. At that time bacilli lodge in the gall bladder and urinary bladder living there for months or years, and possibly from these parts come most of the late typhoid and post-typhoid lesions, the gall bladder discharging into the bowel regularly thousands of bacilli which may enter the circulation and lodge in any part; or, again, under some circumstances, infection from the urinary bladder may take place. This, briefly, may be the explanation of many of the supposed instances of viability in which 18, 20 or 30 years after an attack of typhoid, bone lesions, gall-bladder infection due to *Bacillus typhosus* occur, or persistence of typhoid bacilli in stools is seen.

Papers were also read by Dr. J. Torrence Rugh on "Joint Complications in Typhoid Fever," and by Dr. E. J. Beardsley on "The Genitourinary Complications of Typhoid Fever." Dr. Francis W. White's report of a case of typhoid spine will appear in The Journal.

DISCUSSION.

Dr. John A. McGlinn: I agree that it is exceedingly difficult to diagnose typhoid perforation. I always feel that it is much better to operate early at the risk of a mistake in diagnosis than to wait for an absolutely sure diagnosis and find the condition beyond hope of recovery.

Dr. L. Jay Hammond: I feel that the present high mortality in typhoid perforations will be lowered by prophylaxis rather than by operation or the let-alone method of treatment. From a careful investigation of the subject made a year or so ago I was led to the belief that in the majority of cases of typhoid perforations there had been adhesions due to preexisting disease, and that in all probability the interference with normal intestinal action, blood supply and peristalsis was a prominent factor in ulceration and subsequent perforation. We are told that during the first week of typhoid fever there are no symptoms referable to the abdomen *per se*. Therefore, given a case of typhoid fever during the first week of the disease with the symptoms prominently those of the abdomen we should strongly suspect an inflammatory condition, probably due to adhesions.

Dr. T. Turner Thomas: I have seen one case of typhoid spine, that of an old man convalescing from typhoid fever. He was taken with severe pain in the back, localized after three or four days in the lumbar spine. The painful condition lasted for a long time, with gradual improvement, and now, after more than three years, there is still a little pain and the back is weak.

Dr. Henry Beates, Jr.: Might not the fact that the typhoid bacillus always dies in rabbit serum give us a method of treatment which might result in destroying the bacillus of typhoid fever?

Dr. Edward J. G. Beardsley: When Gibney reported his case and introduced the term "typhoid spine," he distinctly stated that the term carried with it no pathologic implication; but his suggestion was that a periosteal lesion, inflammatory in character, and caused by the presence of the typhoid bacillus, would explain the condition. Dr. Osler, on the other hand, was inclined to the belief that the condition was a neurosis, and it remained for McCrae to point out that in every case in which an examination was made by *x*-ray, a pathologic lesion could be discovered. Of one thing we can feel sure, and that is that the recovery of the patient depends to a great extent on a correct diagnosis being made and suitable treatment instituted. Many cases of typhoid spine are considered to be lumbago, rheumatism, intercostal neuralgia, tuberculosis of the spine, etc., and faulty treatment advised before the true nature of the disease is discovered. I think it is well to point out that in all cases there is an actual lesion of the periosteum, the bone or the cartilages.

Dr. J. Torrence Rugh: I have a case at present in which operation is necessary to correct a deformity following injury which occurred in a typhoid patient and in whom there is a typhoid spine, and yet I am afraid to operate for fear of relighting the original suppurative inflammation which followed the typhoid infection. When we find that the typhoid bacillus is viable from ten to sixty years in the human body it becomes a matter of the greatest importance to the surgeon who contemplates operation. Typhoid spine is recognized by orthopedic surgeons as a distinct form of infection similar to the infection of the joints, and as a condition which takes on different characteristics in different patients.

BOSTON MEDICAL LIBRARY MEETING.

Regular Meeting, held Nov. 18, 1908.

Dr. Franklin G. Balch in the Chair.

Cancer of the Bladder.

Dr. Arthur T. Cabot: The two things most important are early diagnosis and the removal of the tumor with wide margin. Though early discovery is often difficult, it is rendered possible by the cystoscope. In case of doubt two cystoscopic examinations should be made. Often the disease is far advanced before the patient is seen. Therefore early symptoms should be watched for. These are intermittent hemorrhage, pain, frequency and urgency of micturition. Hemorrhage is the most constant early symptom, while frequent micturition, which oftenest sends the patient to the doctor for advice, is often only noticed when the disease is already well advanced. Under the microscope a urinary sediment which shows blood, particles of villi and clumps of atypical epithelium helps in the diagnosis. Cystitis is a medical disease, but is often referred to the surgeon, who will wisely look into every bladder where there is the slightest doubt. Probably all papillomata become cancerous unless early treated and removed. This may be done through the cystoscope, but incompletely. It is better to make an open incision and remove with a wide margin by actual cautery. Mayo recommends that the tumor itself be lightly cauterized in order to avoid possible contamination of healthy mucous membrane. Careful search should be made for any other tumors and watch kept for other symptoms. Cancer only slowly invades the neighboring lymph glands. Operation on the anterior wall or the fundus is easier than at the base, but the disease is most frequently located at the base. The intraperitoneal route is to be preferred. It gives more room and allows the whole thickness to be removed. If glands are removed because diseased, probably the disease is already too far advanced. The free wall may be removed to a surprising extent. Operation at the base is difficult, mortality is high and cure doubtful. Recurrence is frequent, but operation may be successful with small growths. One of the most serious problems is the care of the ureter, whose mouth is often involved in the operation. Reimplantation is difficult. Temporarily it may be put at the upper angle of the wound. Later a nephrostomy may be done and drainage established. Palliative operations are useful. Curetting and cauterizing often yield long periods, even years, of relief. Double nephrostomy has been proposed in order to give the bladder rest.

DISCUSSION.

Dr. F. S. Watson: I have made a study of all cases reported up to 1908, a total of 683 cases. The cures in the supposed benign cases have been few and the deaths following operations in the malignant cases many. Therefore, probably many, perhaps all, of the benign cases have been but the beginnings of cancerous growths and have recurred as such when not thoroughly removed. The high mortality seems due to lowered vitality, shock and renal infection. To reduce shock and the chance of renal infection a preliminary double nephrostomy should be done. Do not try to implant the ureters. By using a belt it is possible to keep the patient dry.

Dr. F. B. Harrington: I favor the intraperitoneal route for operation as I outlined it in 1893 and which I have developed since then.

Dr. Paul Thorndike: I have had fifteen cases of tumor of the bladder: none of these was benign and twelve were so disseminated that only total extirpation could be considered. Of the three patients operated on, one had recurrence on the posterior wall in nine months, one on the side wall in five months and one was lost track of. Palliative operations do not prolong life, but do greatly increase comfort, so that the patient dies of the cachexia and for long periods is free of pain. The intraperitoneal route is preferable to the suprapubic and nephrostomy to ureteral implantation.

Dr. Hugh Cabot: I believe in palliative treatment. A study of twenty-five cases shows that patients so treated have on the average a year of perfect comfort and six months more of comparative comfort. One of my patients had great relief for eight years. Those cases which heal rapidly do best in this respect.

Cystitis.

Dr. Arthur L. Chute: The subject may be divided into (1) acute cystitis, (2) chronic non-tuberculous and (3) chronic tuberculous. The acute form is the common one and due oftenest to extension from the urethra or kidney, to catheterization or to infection through the blood stream or lymphatics. Bacteriuria does not necessarily cause cystitis. It is specially important in each case to determine the predisposing cause. Still more important is this in chronic cases. Chronic cystitis is a form without the urgent features. Pus, however, is always present. Diagnosis from chronic kidney suppuration may be difficult. Cystoscopy may be necessary or even catheterization of the ureters. If after a bladder irrigation the urine next passed contains much less pus the diagnosis of cystitis is confirmed. Search should be made for the predisposing cause, such as disease of the kidney, antiflexed uterus, stone in the bladder, etc. Prognosis is good only if this cause can be removed. If untreated, cancer or fatal pyelonephritis may result. The lesion in the bladder wall is apt to involve deeper layers than the acute process. Suprapubic cystotomy may be necessary. Urinary antiseptics are of doubtful value. Irrigations are valuable but have their dangers. Where other methods have failed, opsonic treatment is likely also to fail. The tuberculous type occurs mostly in young adults for no known reason, is secondary usually to kidney disease, and gradually grows worse. Diagnosis is made by finding the tubercle bacillus. Treatment is directed first to the tuberculous kidney and afterward to the cystitis.

DISCUSSION.

Dr. Edgar Garceau: In diagnosis of cystitis hemorrhage is the principal symptom. Bimanual examination of women will sometimes show the presence of infiltration in the floor of the bladder and suggest malignant disease. Catheterization is a delicate operation, the soft rubber catheter being much safest. After nephrostomy it may still be wise to treat the bladder and not merely rely on rest. In chronic cases the patients are often helped and may even be cured by change of climate and attention to hygiene. Cystotomy ought to be done much more often than is now the custom.

Medicolegal

Corporations Other than Hospitals, Etc., Are Prohibited from Advertising to Practice Medicine.

The Court of Appeals, the court of last resort in the state of New York, has, in the case of People vs. John H. Woodbury Dermatological Institute, affirmed the judgment of conviction of the defendant of the crime of unlawfully advertising to practice medicine in violation of the provision of the statute of that state that "any person not a registered physician who shall advertise to practice medicine, shall be guilty of a misdemeanor."

The court says that it was argued that the context in the general act of 1907 regulating the practice of medicine, which contains the prohibition against advertising to practice medicine by any person not a registered physician, indicates conclusively that "any person" therein mentioned could not possibly have been intended to mean "any corporation."

The great difficulty in the adoption of a construction making this statute apply to corporations grows out of the existence of hospitals, dispensaries, and similar corporate institutions, which are unquestionably authorized by law to practice medicine, although, of course, only through the agency of natural persons who are duly registered as physicians. But the objects for which the defendent was incorporated were stated in the certificate of incorporation to be: "The carrying on of business of manufacturing chemical preparations and printing, publishing and selling books and pamphlets, relating to the same and advertising same." There could be no suggestion or pretense that this was a hospital corporation or dispensary.

In reference to hospitals and dispensaries, it could hardly have been the intention of the Legislature in the act of 1907 to prohibit such corporations from advertising to do what they might do lawfully—that is to say, from advertising to practice medicine; yet it was argued that, if the court held that the act of 1907 made it a misdemeanor for any corporation (making the term "person" embrace a corporation) to advertise to practice medicine, it must also hold that incorporated hospitals and dispensaries fell within the prohibition. If this were the necessary result of the construction adopted, it would furnish a strong reason for rejecting that construction.

It seems to the court, however, that it can affirm this judgment without in any wise denying the lawful right of hospitals, dispensaries, and similar corporate institutions to advertise their readiness to exercise their lawful functions; and this simply for the reason that the general medical law of 1907 is obviously not intended to apply to the case of such corporations at all. In other words, the prohibitions therein contained against the practice of medicine without lawful registration in New York state, or in violation of any of the provisions of the statute, or against advertising by any person not a registered physician, were not intended to apply and plainly could not reasonably be held to apply to corporate bodies which by the express provisions of other statutes are authorized to carry on the practice of medicine on compliance with their provisions and without registration.

The incorporation of hospitals is provided for in Section 80 of the membership corporations law of New York. An institution of this character, possessing legislative authority to practice medicine by means of its staff of registered physicians and surgeons, comes under the direct sanction of the law in so doing, and by the plainest implication, under well-settled rules of statutory construction relating to enactments dealing with the same general subject matter, is excepted from the operation of the act of 1907 under which the defendant was convicted.

It was suggested in behalf of the defendant that to attribute to the Legislature a design to prohibit a corporation which was not registered as a physician from advertising to practice medicine was to charge the lawmakers with doing an absurd act, inasmuch as it is impossible under the law for a corporation to register as a physician. There is nothing in this point. It might just as well be urged that there is no need of a law prohibiting a minor from voting, since everybody knows that a minor has no legal right to vote. This fact does not prevent illegal attempts on the part of minors to exercise the right of suffrage, and the facts in the present case show that a corporation may undertake to practice medicine without authority of law.

Cancer of the Womb Not a Disease Peculiar to Women.

The St. Louis Court of Appeals says that in the case of Shuler vs. American Benevolent Association, an action on a policy of health insurance, the policy provided that insurance under it should not extend to or cover diseases peculiar to women, and it was contended that the sickness of the insured being alleged to be cancer of the womb, was a disease peculiar to women. But the court does not agree with that contention. The disease itself, the court says, was not shown, and in fact could not have been shown, to be peculiar to women, for it is common knowledge that it attacks men as well as women, and the fact that it at times shows itself in an organ possessed by women and not by men does not make it a disease peculiar to women, for it could not be peculiar to women unless men are immune from its ravages. The court thinks that the correct interpretation of the provision in the contract exempting the association from liability for sickness caused by diseases peculiar to women, covered only such diseases as women have, and from which men are immune.

Local Rights Regarding Establishment of Contagious Hospitals.

The Supreme Court of Michigan says, in the case of Summit Township vs. City of Jackson, that the charter of the city, as revised in 1905, provides that the council may purchase the necessary lands and erect thereon, or otherwise provide, one or more hospitals, either within or without the city limits, and provide for the care and treatment therein of such sick and diseased persons as the council or board of health of the city shall deem proper, and by direction of the council or board of health persons having malignant infectious or contagious diseases may be removed to such hospital, and there detained and treated when the public safety may so require.

The township contended that this should be construed as requiring the city to obtain the consent, license, and permission of the proper township authorities, before it could maintain a smallpox or other hospital for the treatment of infectious and contagious diseases or bring patients infected with such diseases within the limits of an adjoining township. The city insisted that it conferred on it a governmental function and right which carried with it the right to use any site selected for the purpose indicated without reference to the consent or objection of the municipality in which the same might be located. The court inclines to the former construction, holding that the city could not bring patients infected with dangerous communicable diseases within the township without first obtaining consent therefor from its proper officers according to law.

The court says that by the general health laws of Michigan townships have been authorized to acquire sites for hospitals in other townships, but the right has always been subject to the consent of the township where the hospital is to be located. Cities by their charters and fourth class cities under the general law, have been given the naked right to acquire extraterritorial sites for contagious disease hospitals, for the reason that, without such legislation, such municipalities had no authority to do so. Nothing is said in any of these acts relative to the consent of the invaded township. But the construction that the authority to acquire hospital sites without their limits is an authority granted to cities and villages for the purpose of giving them a recognized benefit already enjoyed by townships generally, leaving them, as to the exercise and enjoyment of such benefits, to be governed by the general health laws in force on the subject, will comport with the well established doctrine of local self government of each municipality within its limits. Such construction is a reasonable one. It will preserve to each municipality the provision for the prohibition of the entrance of person, corpse or thing infected or suspected of infection with any dangerous communicable disease within any municipality, without the consent and supervision of its health officials, which has been the greatest safeguard of the public health.

There is no express indication in the Michigan legislation relative to the public health that municipal boundaries are disregarded and other or different districts established. The cities and townships within their respective limits are, in the execution of the laws relative to the public health, exercising a governmental function or agency. There is no authority of law given to one to invade the territory of any other, and there is grave doubt whether legislation which expressly granted such authority could be upheld. However, it was not necessary to determine that question in this case.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

New York Medical Journal.

December 5

1 Etiology of Dementia Praecox. M. J. Karpas, New York.
2 *Peritonitis Due to Appendicitis. F. Torek, New York.
3 Cholera and Commerce. W. T. Jenkins, New York.
4 Restoration of Sight After Nearly a Month's Blindness from Glaucoma. J. L. Minor, Memphis, Tenn.
5 Value of the X-Rays in Chest Diagnosis. A. L. Gray, Richmond, Va.
6 *Congenital Nephritis. H. T. Karsner, Philadelphia.
7 Glioma of the Brain Involving the Pia Mater. I. Strauss, New York.
8 Case of Fracture and Dislocation of the Second Cervical Vertebra. C. D. Fox, Philadelphia.

2. **Appendicular Peritonitis.**—Torek discusses the various forms of appendicular peritonitis, especially diffuse suppurative peritonitis, and reviews the various methods of treatment devised. He describes in brief outline his own method (fully detailed in the *Medical Record*, Dec. 1, 1906, and abstracted in THE JOURNAL, Dec. 15, 1906, p. 2035), and explains the purpose of the large median incision, the cleansing by irrigation, and the closure without drainage.

6. **Congenital Nephritis.**—Karsner reports a case in which a child that died 45 minutes after birth showed nephritis. The mother's history and physical examination were negative, and there was no indication of syphilis. The idea (as the woman was unmarried) that some drug might have been used to induce abortion was not overlooked, but no supporting evidence could be obtained. The child was also a "blue baby," so that it is not known how far the kidney condition was responsible for its death. Karsner has found only three cases on record in which infants have truly been born with nephritis.

12 *Care of the Mouth During Infancy and Childhood. W. J. Lederer, New York.
13 *Special Provisions for Management of Certain Forms of Mental Disorder. A. Gordon, Philadelphia.

9. Abstracted in THE JOURNAL, Nov. 7, 1908, p. 1627.

10. **Neurasthenia.**—Rockwell, while protesting against the too indiscriminate diagnosis of neurasthenia, is yet a firm believer in the propriety of classifying under this head a great family of symptoms. Their infinite variety is marvelous, but while all do not coexist all will be found distributed among various subjects. In the majority of cases, though not in all, there is undoubtedly an hereditary tendency. When that is strong neurasthenia may develop without any apparent exciting cause, even so early as puberty. It takes years of evil indulgence to wreck the nervous system in a strong man, so that subjects of acquired neurasthenia are usually older. The effect of alcohol and drugs is largely a question of nervous stability. Hysteria is not neurasthenia, which indeed is met with in women far less frequently than in men. The sexual excesses that lead to neurasthenia are rarely those

of legitimate marriage relations, but are either perverted forms, or those of irregular sexual relations. The one overmastering symptom associated with a neurasthenic state is morbid fear. The author details the various classified phobias. As to treatment, with regard to rest cure or work, intelligent differentiation is needed. Cerebral excitement associated with physical exhaustion imperatively demands rest. In the lithemic—hearty eaters who suffer from autoinfection, whose irritability and unreasonable outbursts of temper differentiate their case from the mild melancholy of the neurasthenic of an entirely different type—work and activity in plenty are oftentimes the saving grace. While success rarely depends on drugs, their judicious employment is sometimes useful. The author mentions particularly zinc bromid, alone, or with belladonna, cannabis indica, etc. Of all physical methods he regards electricity as of the most positive value in neurasthenia. The influence of light and heat have been found useful. Mental therapeutics is without doubt an important factor in many cases. Rockwell relates an instance of gynephobia in which he initiated a cure, by himself taking the patient to a department store and compelling him to make purchases from the shopgirls.

12. **Care of the Mouth.**—Lederer discusses the development of the mouth and teeth and the importance of oral hygiene. Parents and guardians are woefully lacking in knowledge thereof, and the busy general practitioner does not realize its importance. Boards of health should cause children's mouths to be examined, and then the family physician should take up the work. He suggests the appointment of a stomatologist on every hospital staff. It is important before operation to have cleaned out not only the bowels, but also the other end of the alimentary tube.

13. **Mental Disorder.**—Gordon urges a careful discrimination of the overwhelming multitude of mental disorders with reference to the method of management. The insane asylums, as at present organized, are suitable for incurable psychic infirmities, but do not meet the material or moral requirements of recoverable maladies. It is important to avoid subjecting, for instance, patients with mild melancholia to an insane environment, and to the stigma that accompanies those who have once been in an asylum. Gordon urges the formation of a special mental disorder service in general hospitals. A patient in the hospital becoming unmanageable from delirium, etc., could be removed to this service, and when mentally fit again should be restored to his former service. These special services, moreover, could be used in the case of individuals suddenly developing a confusional state, which demanded observations. Should the case prove incurable, the patient could be transferred to an asylum. If curable, the treatment could be continued and the patient ultimately discharged well, with the thought that he had been treated in a general hospital. Special wards also would be of great educational value. The economic problem he considers solved by setting off against the expense the reduction in the enormous expense of overcrowded asylums with very little or hardly any result so far as treatment is concerned.

15 *Practical Notes on Vesical Tumors. G. F. Lydston, Chicago.
16 Multiple Serositis. W. L. Bierring, Iowa City, Ia.

14. **Organotherapy.**—Edsall meets the objections to organotherapy based on a scornful charge of empiricism. The objections apply only to the lucky shot form of empiricism, the mystic form, and the form in which extensive speculation is built on a small basis of scientific fact. That form of empiricism, however, which consists in collating carefully observed facts and their apparent relation to other facts, even though it may be insusceptible of explanation, serves a good purpose in medicine, in the absence of more scientific knowledge. Edsall discusses organotherapy from this standpoint. The instability of the preparations and the fact that their natural supply by the organism is in small continuous doses while, unless we transplant organs, we are compelled to administer them only more or less occasionally, so that their effects are transitory, have to be overcome. Edsall suggests that this may be done by producing artificial substances that resemble the natural stimuli closely in their constitution and retain the desired activities, but have differences in structure that render them more stable and prolong their effects.

15. **Vesical Tumors.**—Lydston emphasizes the following points: 1, The importance of an early diagnosis; 2, the urgency of early operation; 3, the necessity of reliance to a great extent on clinical experience, rather than on the microscope for a diagnosis. In the absence of other more or less positive explanations, prolonged pyuria of vesical origin is likely to mean stone, tumor or tuberculosis. An early diagnosis is important in all of these conditions. More important still is the fact that an early diagnosis of bladder tumor, followed by immediate operation, may forestall the transition of a non-malignant into a malignant neoplasm. The dissenters from this view are chiefly laboratory men rather than clinical observers. Lydston insists on the possibility of the transition of syphilitic new growths into malignant. Under certain varieties and degrees of irritation the histology of a non-malignant neoplasm is altered by displacement and replacement of benign histologic elements by those of malignant disease. The process resembles to a certain extent that which is erroneously termed in Nature petrifaction.

23. **Alimentary Albuminuria.**—Croftan means by alimentary albuminuria, the passage of native food albumin as such, unchanged from the alimentary tract into the urine. He describes the method of performing the precipitating reaction therefor. The fact he emphasizes is that one should learn to recognize the existence of a distinct and well-characterized form of albuminuria of rather favorable prognosis that is not due to a nephritis of toxic or infectious origin, to circulatory disturbances in the kidneys, to general cardiorenal disease (Bright's disease in the modern sense), but is due primarily to digestive disorders of a certain type. We are dealing here with an exclusively enterogenous albuminuria in the interpretation of which the renal idea proper should be largely relegated to the background and in which treatment should not, as in Bright's disease, be directed chiefly against disturbances about the general metabolism and the cardiovascular apparatus, but against a well-characterized perversion of the gastrointestinal and hepatic functions.

24. **Diagnosis of Lobar Pneumonia.**—Reilly, struck by the great weight of hepatized lung, instituted careful questioning among patients suffering from lobar pneumonia, and found

that as soon as the sensation of acute pain due to the accompanying pleural affection has passed off, most patients state that they feel a sense of weight or load on the affected side Reilly regards this as a valuable sign in the early diagnosis of lobar pneumonia.

33. **Peculiar Characteristic of Spirochetes.**—Butler, in endeavoring to keep the spirochetes in African tick fever alive and active outside the body, found that there develop on the bodies of the spirochetes, with few exceptions, small nodules generally about the mid portion of the organism, but occasionally toward one end, varying in size from 1 to 3 microns, and many of them containing one or more granules which undoubtedly took the chromatin stain (Romanowski's). The nodule is organically a part of the spirochete. The author says that if these bodies really show chromatin ducts—and it certainly seems that they do—the spirochete must be a protozoan and not a bacterium It clearly is not a spore. Microphotographs accompany the article.

34 **Samoan Conjunctivitis.**—Rossiter, thinking it unlikely that in a region where gonorrhea of the genitourinary tract is quite rare, the great frequency of a severe conjunctivitis should be attributable to that disorder, investigated the condition. He terms the prevalent type 'Samoan conjunctivitis," describing it as 'a distinct, acute infectious disease characterized by rapid onset, severe pain, photophobia, a high grade of conjunctival inflammation (soon becoming purulent), a tendency to corneal destruction over greater or less areas; and the presence in the discharge often in pure culture of its etiologic factor, a distinct micrococcus" The author holds it to be probably the *Micrococcus catarrhalis*. The various salts of silver present the best treatment.

35 **Potable Water.**—Noyes says that in works dealing with water examination and analysis, 'figures are generally given which indicate either (a) the average analysis of a large number of waters, both pure and impure, or (b) the largest quantity of the different ingredients found in waters known to be pure; or, again, it may express (c) the quantity of a substance which a pure water might reasonably be expected to contain, or it is the largest quantity which an authority deems safe, not that the substance itself is deleterious, but because an amount in excess of that given would in all probability indicate pollution" The author compiles a table giving access to such figures by recognized authorities of equal repute and from this he makes a composite, by taking the highest figures under each heading to represent what the average potable water may contain By this standard he tests nine waters of known character and origin, under which test such a composite standard breaks down; known polluted waters appearing as potable, and *vice versa*. He next investigates the significance of individual ingredients and their relation to pollution In regard to the nitrogen content, he shows that albuminoid ammonia, even in large quantity, does not of itself indicate pollution, nor does its absence insure purity; that the presence of free ammonia does not prove, and its absence does not preclude pollution; that the presence of nitrites is not positive evidence of pollution, or their absence by any means proof of purity; and that the presence or absence of nitrates gives no definite information as regards purity. He further shows that the presence of chlorin can not of itself definitely determine pollution, for while small amounts are the more common, it is not difficult to find a pure water containing a very large measure of chlorids Finally, the oxygen consuming power alone tells us nothing; for a pure water containing vegetable matter will have a high oxygen-consuming power, while an extensively polluted one may consume but little. To suggest a means of determining the quality of water, he reviews the natural course of water from the clouds to the spring, and states that, if on analysis, we find an increase in the quantity of any one or all of the nitrogenous products over that contained in the pure water from a like source in the same neighborhood from which the specimen comes, and if the chlorin remains unchanged, then the water has suffered in quality by the addition of vegetable matter, but it is not polluted If, however, there is an increase in the quantity of one or all of the nitrogenous products, and at the same time there is an increase in the chlorin, then animal matter has been added and the water is polluted and dangerous As is apparent, such a method for determining purity requires a complete sanitary analysis

38. **Mercurial Injections in Tuberculosis.**—Hayden reports four of the most encouraging cases of treatment of advanced tuberculosis by hypodermic mercurial injections, as recommended by Wright. In one case there were advanced tuberculous lesions of both lungs when the mercurial treatment was begun The patient had been given up, not only by his relatives and friends, but also by the hospital staff. He was bedridden, and the attending physician expected his death within a month; yet within two months all his symptoms had disappeared, he was able to walk around by himself, although 83 years of age, and had gained 33 pounds He is now presumably well and Hayden expects him so to continue.

42 Clinical Use of Hypnoidization in Treatment of Some Functional Psychoses J E Donley, Providence, R I
43 *Rationalization in Everyday Life E Jones
44 Experimental Study of Sleep B Sidis, Brookline, Mass

41. Abstracted in THE JOURNAL, July 11, 1908, p. 163.

43 **Rationalization in Every-Day Life.**—From Freud's researches, Jones says, comes the demonstration that a number of mental processes in a normal person owe their origin to causes unknown to and unsuspected by the individual The importance of feeling in the moulding of judgments, beliefs and conduct, has for centuries been recognized by poets and writers, but allotted by academic psychology a very subordinate position in regard to the intellectual processes. Not only are the causes of these mental processes frequently unsuspected by the individual, but they are repudiated and denied when the mere existence of them is suggested. The concealment mechanism may be studied in two ways: 1. The known feeling processes may be traced from their origin to the changed form in which they appear in consciousness and their effect on associated mental processes thus observed; or 2, a given mental process may be analyzed and its causes traced back to their elementary sources While these mechanisms are numerous and complex, they may be grouped into two great classes, according to whether the individual is willing to offer an explanation as to the origin of the terminal mental process or not. Inquiry is stopped in either case, because in the one case he already has an explanation; in the other, he thinks one does not exist, and considers the given mental process self explanatory and inquiry as to its origin absurd, unnecessary and fruitless We may conclude that whenever an individual considers a given process too obvious to admit of investigation into its origin, and shows resistance to such an investigation, we are right in suspecting that the actual origin is concealed from him, almost certainly on account of its inacceptable nature. This criterion applies to an enormous number of our fixed beliefs—religious, ethical, political and hygienic—as well as to a great part of our daily conduct. Yet if such beliefs and conducts are to be brought into scientific harmony, it is important that the mechanism controlling them should be made the subject of precise study. In regard to the first class, where the individual proffers an

explanation, but a false one, it is only another aspect of the necessity every one feels to have what may be called a theory of life, particularly a theory of himself. No man admits that he deliberately performs irrational acts. Any act that might appear such is justified by distorting the mental processes concerned and providing a false explanation that has a plausible ring of rationality. Two different groups of false explanations occur, according as they are formed essentially for oneself, or in special reference to the opinions of one's circle. The author's purpose has been to illustrate from what diverse sides Professor Freud's principle may be supported, and to indicate the vast field over which it yet remains to be applied. We are beginning to see man not as the smooth self-acting agent he pretends to be, but as he really is, a creature only dimly conscious of the various influences that mould his thought and action, and blindly resisting with all the means at his command the forces that are making for a higher and fuller consciousness.

54 Ists and Isms. C. P. Brown, Chickasha, Okla.

51. **Railway Sanitation.**—Stolper reports results of an extensive and systematic study of railway sanitation. His investigations are based on a personal acquaintance with sanitary conditions of every railroad in the United States, Mexico, Canada and many countries in Europe; a personal knowledge, due to personal discussions with them of the attitude of every president and vice-president and most general managers of railways in the United States, and many years of careful study of the whole subject, in which he secured the cooperation of every railroad in the United States. He studied the following four questions:

1. What is the existing sanitary state of steam and street cars and depots?
2. What share, if any, have railways in the spread of disease?
3. Sufficiency or insufficiency of sanitary legislation?
4. Who is responsible for existing sanitary conditions on railways?

To answer these questions every railroad on the North American continent, except Alaska, was personally inspected by Stolper, in reference to (a) conditions of depots and passenger cars, dining rooms, lunch counters and dining cars; (b) facilities for cleaning and cost of cleaning equipment; (c) regulations to enforce sanitation adopted by each individual railroad company. His findings are as follows:

1. The sanitary conditions existing on steam and electric street railways and depots are bad.
2. What share, if any, railways have in the spread of disease, can be answered only problematically, for there is no definite way of collecting statistical data.
3. Specific sanitary regulations and legislation have so far been enacted in very few states. The leader of such states is Texas, followed by Wisconsin, Minnesota, Kentucky, and a few others, but while the majority of states have no specific sanitary legislation, every state board of health has the power to enforce sanitation on railways under and within the general police of the state.
4. The responsibility for the bad sanitary conditions on our railways rests primarily with the traveling public; secondarily with our public authorities, especially boards of health and police officers.

He considers the following points as of material importance in promoting sanitary conditions on American railways:

1. Abolition of the drinking cup.
2. Screening of all windows and doors of railroad cars.
3. Abolition of through car service: no passenger car should be in use longer than twelve hours.
4. Trains going through San Antonio, Texas, Arizona, New Mexico, Southern California and in the Carolinas and all other health resorts should carry Pullman cars of the Canadian Pacific type.
5. Water tanks to be made of the Chicago, Burlington & Quincy type.
6. All floors to be covered with non-absorbable paint.
7. Handling of ice for ice water with steel tongs, by a man wearing clean rubber gloves, the ice being washed by a stream of water from a hose.
8. A medical sanitary officer, especially trained in sanitation, who should be in charge of the cleaning of all railroad cars and all sanitary matters, on each railroad line, and who should report directly to the head of the operating department, preferably to the president of the road.
9. Supervision of the sources of the water and ice supply by the sanitary officers above described.
10. Abolition of the use of silk, wool or plush from railroad and Pullman cars.
11. Placing of the inner doors in cars at a different angle from the outside door, so that the cold air would not reach the sleeping passengers at night.
12. The train porter should have no other duties but to look after the physical cleanliness of the train, and should be a brakeman.
13. Adoption of a system of heating which could be regulated by passengers and not have to depend on busy train crews.
14. Also of a system of ventilation that would keep out the coal smoke and gases from the cars while in trains.
15. Every car should be disinfected with formaldehyde gas in the presence of ample moisture.
16. The toilet rooms should be enlarged, especially for women, on Pullman cars.
17. Every railroad company should operate its own sleeping cars, and the cost of sleeping car accommodations should not be above what such service would cost at hotels.

62. Abstracted in The Journal, Oct. 17, 1908, p. 1360.

63. **Mineral Waters.**—Weiss discusses the physical, chemical and therapeutic properties of mineral waters. The observed fact, that carbonic acid gas escapes far more slowly from the water of natural acidulous springs than from artificial waters, is supposed to be due to the presence in natural waters of bodies capable of hypersaturating themselves with carbon dioxid, called "catalisatories." Possessing no intrinsic chemical properties themselves, they are capable of materially assisting extrinsic chemical reactions occurring in the same solution. One 360,000th of a milligram of platinum will promote decomposition of 1 c.c. of hydrogen peroxid. These energies are comparable to those of the enzymes in plant life, the elucidation of which has been greatly promoted of late by a comparison of synthetic with natural processes. Excellent results have been obtained with simple means. Weiss urges the submission of these catalisatories to careful and accurate investigation.

73. **Gastroptosis.**—Laplace says that the nutrition of tissue forms the basis of physiologic equilibrium, the disturbance of which results in altered tissue resistance. Perfect nutrition maintains the ligaments in proper tonicity, while imperfect nutrition weakens them and allows the weight to be sustained by them to stretch them beyond endurance. Beyea's operation of shortening the ligaments by free rows of interrupted sutures is a good one in immediate results, but its later effects are bad; so Laplace endeavored to improve on the method by supporting the stomach in a normal position from above and below. He devised as an adjunct to Beyea's operation a method of suturing the gastrocolic omentum to the anterior abdominal wall by a continuous catgut suture, after gently scarifying the surfaces to be brought into apposition. The stomach is thus supported from below.

74. **Prevention of Retroversion of the Uterus After Childbirth.**—Davis says that congenital retroversions and those arising from lack of developments are difficult to correct after childbirth. It is important that labor be so conducted that overdistention of the ligaments and fascia, which maintain the uterus in its accustomed position, shall be avoided. Deep lacerations of the cervix and vagina extending into the fascia should be repaired immediately. Lacerations near the utero-sacral ligaments are especially important. During the first forty-eight hours after labor the uterus should be maintained in position by gauze packing. During the puerperal period the patient should change her posture frequently, avoiding lying long on the back. Patients should not get up too early after childbirth. After the lochial discharge has ceased, the knee-chest posture, night and morning, will greatly aid in restoring the uterus to its proper position. When there is a disposition to retroversion the patient should wear a pessary as soon as she begins to get up. Such patients should be kept under observation for several months at least. When the uterus does not assume its normal position and maintain it, intraperitoneal shortening of the round ligament by Gilliam's method should be performed.

1. **Diabetes.**—Pavy reviews the growth of the evolution of our knowledge of diabetes, and concludes that everything points to the existence of a missing link in the chain of events thus far reckoned to occur in connection with the passage of carbohydrate from the seat of absorption in the walls of the alimentary canal to that of utilization in the tissues.

2. **Heredity in Nervous Diseases.**—Gowers holds that the scientific study of heredity can not be applied fully to the diseases of man, for the human race is not open to Mendel's essential methods, and its mere complexity of development involves innumerable differences from lower forms of life, the effects of which may be greater than we can realize. In diseases that are merely in, not of, the nervous system—tumors, defective developments, etc.—though heredity may be held likely, it can not be directly connected with them. Sudden cerebral seizures, etc., depend on causes that take their heredity far from the brain in which the lesion occurs, yet the frequency with which heredity is active is notable. A class of diseases in which heredity is potent is those which consist of deranged chemical processes in the vital laboratory of the human frame giving rise to endogenous toxins, e. g., diabetes. Diseases of the nervous system in which the influence of heredity is marked seem to fall in certain classes. 1. The early "abiotrophies," a term applied by Gowers to cases in which certain systems of structure in the nervous or muscular system have an essential defect of vital endurance in consequence of which life slowly fails. He instances baldness, hereditary ataxia, pseudohypertrophic paralysis, hereditary nerve atrophy, etc., and cites illustrative cases. In this class the heredity is maternal only. The tendency is thus germinal. The female children seldom suffer in the typical form, but they inherit the tendency and their sons are prone to suffer. In the ova from which the daughters develop, the potentiality of the disease is only in that portion of the protoplasm which will become the germinal tissue for another generation. Gowers says that if the tendency is thus fixed in the germ tissue, and differently fixed, according to resulting sex, does not the fact make it probable that the sex is also predetermined? 2. This class may include hereditary maladies, which begin later in life after the period of growth is over. They present persistent disturbance of function and are commonly hereditary, but from either side. As instances, are mentioned heredo-ataxia of Marie, Huntington's chorea and Thomsen's disease. 3. Heredity is operative in many functional affections, e. g., hysteria and neurasthenia, also in epilepsy and insanity. He excludes from consideration epilepsies

that result solely from organic lesions of the brain, from disease, or trauma, or difficult birth, as not concerned with heredity. He has always acted on the belief that the tendency to convulsion in such acquired cases is not transmissible, and he has never hesitated to permit the marriage of a sufferer and has never had any evidence that he was wrong in doing so. He points out the effects of ignorance and the fact that a supposed stigma often leads to concealment, to show the difficulties of ascertaining the facts of family histories. He discusses the statistics of 2,400 cases of epilepsy in which heredity was ascertained in 39 per cent. of 1,993 males and 43 per cent of 1,207 females.

3 **Heredity in Cancer.**—Bashford prefaces his consideration by pointing out that in recent years a great deal of new evidence has been accumulated in support of the view that a malignant new growth contains nothing foreign to the organism attacked. He instances two classes of new facts 1. Carcinoma and sarcoma can be grown continuously only in other individuals of the same species of animals. 2. Investigations into questions of metabolism have shown that the relations of a malignant new growth to its host are merely those of nutrition—of the demand for and the supply of the normal foodstuffs from which tissue is built up and analogous to those obtaining between fetus and mother. He discusses reports rendered to the Imperial Cancer Research Fund during 1906 and 1907 on 2,932 patients suffering from malignant new growths, in which the clinical diagnosis was confirmed by microscopic examination; and concludes that "with nothing but negative evidence of the part played by inherited constitutional conditions before us, and with positive evidence of the important part acquired constitutional conditions can play in furthering the growth, perhaps the development, of cancer, we shall more profitably spend our time if we frankly seek to ascertain how they are acquired, than if we continue to preach the doctrine that they are inherited and that it is hopeless to contend against them."

9 **Organic Nervous Disease.** Bradshaw considers the various aids to the diagnosis of organic nervous disease. As to knee jerk, the real problem in his experience lies in making sure of its absence and not in the interpretation of it. Briskness of knee jerks, as an isolated phenomenon, is rarely of serious moment. Ankle clonus, if sustained, always means organic disease, and may be the only positive indication of it. Absence of the knee jerk, being never due to hysteria or other functional disease, must always be looked on with grave suspicion. Bradshaw believes *that if the knee jerks* can be obtained we may assure the patient with great confidence that he has not locomotor ataxia. Of ocular signs, inequality of the pupils may be normal to the individual. It may, also, he thinks, be a manifestation of uremia. In estimating diplopia we must remember that there is a so-called rheumatic neuritis of the sixth nerve which will be recovered from. Nystagmus suggests organic disease and may indicate disseminated sclerosis in apparently mere hysteria. He regards as true nystagmus only rhythmical and continuous movements elicited without excessive forced deviation of the eyes. It is seldom safe to diagnose locomotor ataxia or general paralysis in the absence of the Argyll Robertson pupil, but this must not be given undue weight; Bradshaw has recently had two patients with this condition without any other indications of organic nervous disease. He further considers bladder troubles, which are so common in individuals with nervous disease, persistent frequency of the pulse in locomotor ataxia, and the so called visceral crises of tabes.

10. **Heredity.**—Drinkwater briefly reviews the theories of heredity and summarizes Mendel's theory. With regard to the inheritance of acquired characters, he holds that the subject is not absolutely settled, but that the most definite facts and precise experimental investigations favor the contrary views of Weismann. Mendel's work is absolutely in favor of Weismann. He discusses DeVries' views of variation, and submits that the various facts that he has mentioned point out with unmistakable clearness the only way by which hereditary disease can be eliminated. We hear about physical deterioration, and great benefit is expected from education and improved sanitary conditions; but neither education nor sanitary laws can eradicate hereditary disease, except by preventing the marriage of affected individuals. Just as a purely brachydactylous race might be produced, so it would be equally easy to eradicate this abnormality by preventing the marriage of the abnormal individuals, and there is little doubt that other hereditary defects and diseases can be practically made to disappear by the same means. Unfortunately, modern legislation tends to the opposite effect, for everything is done to encourage not only the marriage, but the early marriage, of inferior members of the community, while the burdens of taxation retard more and more the marriage of the middle classes. Free education, free meals, free clothing, are all very well for a certain class, but they are not remedies, and the net result to the nation in the long run will be detrimental.

11 See Abstract No 2.

16. **Specific Eruption in Pneumonia.**—Pope records a case of pneumonia in which a crop of papules was observed on the upper part of the back. They were deep rose color, circular, from three to four millimeters in diameter, darker than the average typhoid spot, and disappeared completely on pressure. In three days the first crop faded and a second crop appeared. In another three days they became pustular. Examination of pus showed pneumococci only. The resemblance to smallpox is commented on, though no vesicular stage was noted.

17 **Seasickness.**—Elder reports a case to emphasize the importance of not overlooking extraneous *causes, especially* unsuspected pelvic conditions in women in dealing with seasickness.

32 Bacteriologic Observations on Colon Bacilli Infecting the Urinary Tract, Especially Colon Bacilli of the Anaerogenes Class W J Wilson

25 **Fatness and Caisson Disease.**—Boycott and Damant record elaborate experimental studies by which they are led to conclude that fatness increases the susceptibility to death from

Caisson disease. The practical conclusions are clear. Really fat men should never be allowed to work in compressed air, and plump men should be excluded from high pressure caissons (e. g., over + 25 pounds), or in diving more than about 10 fathoms, and at this depth the time of their exposure should be curtailed. If deep diving is to be undertaken, or caissons worked at pressure approximating to + 45 pounds, thin men should be selected. It is unfortunate that an increase of experience and skill in technical operations should so often be associated with the increase in waist measurement which accompanies the onset of middle life. Middle-aged men have a lower rate of respiratory exchange than young men; if fatness is not the explanation of this, they are at a double disadvantage, and the two factors must be multiplied, rather than added, together.

26. **Abnormal Reaction to Horse Serum.**—On the basis of 50 cases of cerebrospinal fever treated with four different curative sera, all derived from the horse, Currie finds that:

> The total volume of serum given did not affect the frequency of abnormal reactions
> The total number of injections of serum, in certain cases, may have been a factor in inducing abnormal reactions
> The interval of time between the injections concerned was the primary influence in determining abnormal reactions
> It was not apparent that a preceding normal reaction predisposed to a subsequent abnormal reaction
> It was not apparent that a large administration of serum within the latent period predisposed to a subsequent abnormal reaction

27. **Lead Poisoning.**—Duckering, an inspector of factories, summarizes the investigation of Miss Anderson and Dr. Legg into the conditions of labor in the coating of metal articles with lead or tin. The process is described, and the trades affected are enumerated, statistics of lead poisoning being appended. It is found that inhalation is the principal source of trouble and that long continued absorption of small quantities of lead is a much more important factor than the amount of the dose in causing lead poisoning. The vapor of lead chlorid is continually given up from the tinned article for some time after its removal from the bath.

28. **Drinking Water and Steamships.**—Ruffer and Willmore give a short account of: 1, the laws concerning the supply of drinking water to ships in some of the chief civilized countries of the world; 2, the result of bacteriologic examination of the water on 62 steamships; 3, the chief deficiences in supply and storage which have come under their notice; and 4, the reforms which they consider urgently necessary. They make the following recommendations:

1. Ships should be allowed to take water only in places licensed by the medical officer of the port.
2. The hoses, pumps, water boats, etc., should be the property of the port sanitary authorities, who would then be responsible for the proper storing and cleaning of such apparatus. Should this be impossible, no apparatus or water tank should be used until it has been examined and declared satisfactory by the said authority. All the apparatus should be examined and tested once a month.
3. Intake pipes flush with the deck should be absolutely prohibited. They should be replaced by upright iron pipes, three feet high, of standard gauge, having their free ends bent downward and fitted with screw cap chained to the pipe. When in use the cap should be removed and the hose screwed on. Some simple device would indicate when the tank was full.
4. All water tanks on board ships should be made of iron, and coated inside with cement.
5. All water tanks should be placed so as to allow inspection at any time during the voyage.
6. All water tanks should be so closed as to avoid all chances of contamination during the voyage.
7. All water tanks should be fitted with ventilating pipes which should be carried up to a sufficient height to prevent contamination.
8. One or more taps should be placed through the floor of tanks to insure the latter being completely emptied at regular intervals. The tanks should be constructed with "round" corners," the floor of the tanks should be sloping toward the taps used for emptying the tanks.
9. The tanks should be completely emptied and disinfected after each voyage. The methods used at present for this purpose are extremely unsatisfactory. Some form of gaseous disinfection would probably give the best results.
10. In order to insure these rules being carried out, an international agreement is necessary.

35 Spirochetosis in Southern Arabia and the Morphology of the Parasite. R. M. Carter.
36 *Value of Taking the Specific Gravity of the Blood During Saline Transfusion in Cholera. F. J. O'Meara.
37 Treatment of Uncomplicated Lobar Pneumonia. G. M. Smith.
38 *Treatment of Smallpox by Large Doses of Hydrargyrum Cum Creta. V. B. Nesfield.

33. **Immature Cataract.**—From a consideration of his experience in 20,000 cataract extractions, Smith considers:

1. Extraction of immature cataract by the capsulotomy method is hardly justifiable.
2. Ripening procedures are either unsatisfactory or dangerous.
3. To wait for Nature's maturing process is highly unsatisfactory and detrimental to the patient.

His treatment of immature cataract, which he regards as the procedure of the future, and which will make mature senile cataract a much rarer condition than it is at present, is extraction of the lens in its capsule. He describes the method he follows.

36. **Saline Transfusion in Cholera.**—O'Meara urges that more accurate and better results can be obtained during intravenous injection of salt solution in cholera by examination of the specific gravity of the blood, rather than by observation on the blood pressure, for the following reasons:

1. The whole treatment of the disease turns on the increased specific gravity of the blood.
2. An enormous quantity of saline solution may be transferred into the vessels without any marked rise of blood pressure.
3. The peripheral resistance is much increased in cholera, not only by changes in the endothelium of the vessels, but by chemical changes in the blood diminution of oxygen, etc., even independently of the increased specific gravity.
4. The blood pressure in cholera is liable to sudden and considerable variations apart from transfusion, which he is unable to explain.
5. The blood in cholera being deficient both in water and salts, transfusion may temporarily raise the blood pressure with fluid without increasing the specific gravity with salts.
6. By transfusion, gradually regulated by taking the specific gravity, the renal epithelium has a much better chance of recovering its function, and therefore the present large mortality from uremia will be considerably reduced, if not abolished. The most rapid and convenient method for ascertaining the specific gravity of the blood in cholera is that of Hammerschlag, which he describes.

38. **Smallpox.**—The striking resemblance between acute secondary syphilis, as witnessed in India, and smallpox, led Nesfield to employ mercury in the latter disease. He draws the following conclusions from his experience:

1. Ten grains of hydrargyrum cum creta, three times a day by mouth, continued for six days, produces no symptoms of poisoning in smallpox (with natives).

2. The drug appears to have a marked action in modifying and reducing the severity of the disease.

39 Surgical Tuberculosis. B. Poulton.
40 *Abscess Between the Iliopsoas Muscle and the Head of the Femur. R. H. Russell.
41 Treatment of Urethral Stricture. A. Morris.

40. **Iliopsoas Abscess.**—Russell says that the difficulty and obscurity that frequently besets the diagnosis of hip-joint disease is due to the fact that that term covers a group of affections. He describes a syndrome which, in his experience, invariably has been associated with a tuberculous focus in the head of the bone that has opened into and infected the bursa lying beneath the iliopsoas muscle. The position assumed by the affected limb when the child is laid on its back is one of flexion combined with abduction and eversion; in addition, the patient invariably grasps the thigh firmly with the hand of the same side. Russell has never yet been mistaken in diagnosing suppuration of the bursa beneath the iliopsoas on sight in this condition. The explanation is that the iliopsoas is relaxed by the position of flexion, eversion and abduction, but the tendency of the limb to fall outward will have a contrary effect: the patient therefore grasps the thigh to support it and to counteract the tendency produced by gravity.

44 *Functional Kidney Tests in Children. (Élimination rénale provoquée chez l'enfant.) E. Gaujoux.
45 *Nasopharyngeal Origin of Chorea. L. de Ponthière.

44. **Functional Tests of the Kidneys in Children.**—Gaujoux has applied the methylene blue test of kidney functioning in six healthy children between 10 and 14, in eight with recent acute nephritis, and in two with intermittent albuminuria. He used a solution of 1 gm. of the stain in 20 gm. of water, injecting 1 c.c. of the solution in the side of the thigh. The

findings are tabulated and the harmlessness of the test reiterated. It is especially useful to determine whether a nephritis has completely subsided or there still is latent trouble, after the albumin has disappeared from the urine.

45. **Nasopharyngeal Origin of Chorea.**—Ponthière found that a severe chorea in a girl of 9 subsided at once after treatment of inflamed tonsils and adenoids. This occurred twelve years ago, and since then he has frequently found indications for local treatment of the throat in cases of chorea, and invariably the effect was most striking in the prompt subsidence of the chorea. The nasopharynx is the source for infection of various kinds, especially *for the rheumatism infection and for chorea* Enlarged tonsils and adenoids do not always become infected, *and the infection may be of varying virulence and the soil of varying receptiveness*, but the influence on the chorea of suitable treatment of the throat and nose will convince the most skeptical, he says, of the unmistakable connection between them.

46 *Treatment of Operative Pneumothorax in Sound Pleura C Liné
47 Hemorrhoids in Children (Les hémorroïdes chez l'enfant) D G Zesas
48 Stenosis of Intestine Secondary to Strangulated Hernia Mauclaire and Levant

46. **Treatment of Operative Pneumothorax.**—The experiences on record teach that the danger is not so much from the pneumothorax itself as from the possibility of infection. The *pneumothorax rarely proves immediately fatal; there is an* interval of from a few days to three weeks before the patient succumbs, and death is then the result of infection. The pleura reacts to irritation with an effusion, the peritoneum by the formation of adhesions, favored by the frequent points of contact between the intestines and the peritoneum In pneumothorax the lung collapses and one sheet of the pleura retracts with it, leaving a space wider than usual between the two layers, with no points of contact to favor production of adhesions. Every effort should be made, therefore, to avoid infection, and to ward off trouble from this source. Liné gives the details of 25 cases, including several hitherto unreported, all showing that even a total pneumothorax causes no serious disturbances if it occurs slowly and gradually, and if the other lung is working well. He thinks that there is no need for apparatus to induce intrapulmonary positive pressure, as the operation can be done without any such aid, relying on tamponing the pleura during the course of the intervention, artificial respiration as needed, and "harpooning" if alarming symptoms develop If infection occurs and the temperature rises ever so slightly, no time should be wasted in conjectures, but the pleura should be drained at once by resection of a rib and possibly rinsed out There was only one fatality in the 25 cases reported, and the pneumothorax was not responsible for this. Bardesco left the pleural cavity open while removing a sarcoma of the ribs, but the dyspnea and suffocation were slight at the time and later, and all signs of the pneumothorax had disappeared in twenty-five days Delagenière purposely induced a pneumothorax to arrest the hemorrhage in the lung after a bullet wound in the apex, bleeding freely into the air passages. He allowed the air to enter the pleural cavity very gradually and none of the symptoms was aggravated The expectoration of blood decreased and the pulse became stronger. The hemorrhage was definitely *arrested and the patient soon recovered.*

51 *Digestive Disturbances in Rachitis (Troubles digestifs dans le rachitisme) A B Marfan

51. **Digestive Disturbances in Rachitis.**—Marfan has studied for several years the digestive conditions in children with rachitis and in those who develop it later, both in private and hospital practice. The prodromal or initial disturbances are a recurring catarrhal gastroenteritis or a spasmodic dyspepsia with repeated vomiting. The form observed in confirmed rachitis is a dyspepsia from atony with distended, flabby abdomen. Bottle feeding alone is unable to induce rachitis; it is merely a predisposing factor. The real causes of rachitis are chronic infections or intoxications—in the widest sense—occurring at a certain phase of ossification and blood production. This phase extends from the last months of intrauterine existence to the end of the second year. It is during this time that the modifications of the bone marrow resulting from these infections or intoxications interfere with the normal formation and growth of the bone tissue In studying the antecedents of a rachitic child it is only exceptionally that some infection or chronic intoxication is not discovered during this period. The most common are chronic or *recurring digestive toxi infections, prolonged* or recurring bronchopneumonia, multiple and recurring subcutaneous abscesses or prolonged suppuration of eczematous surfaces, and inherited syphilis. These factors act most powerfully on a *predisposed soil, and bottle feeding*, especially when it has been used from birth, and heredity, are the most effectual of the predisposing agents. Subordinate to these are the factors of dampness in the home and deprivation of air and light

53 *Treatment of Chorea by Intraspinal Injections of Magnesium Sulphate (*Traitement de la chorée de Sydenham par les injections intra arachnoïdiennes de sulfate de magnésie)* G Marinesco

53. **Treatment of Chorea by Intraspinal Injections of Magnesium Sulphate.**—Marinesco reports four cases of severe chorea in which the duration of the affection was shortened and there has been no recurrence since the treatment, which was by intraspinal injection of 3.5 c c of a 25 per cent solution of magnesium sulphate. The patients were girls between 12 and 22 years old, and the sedative action of the drug was apparent in a few hours, the symptoms subsiding completely in some, but requiring a second injection in the others Slight by effects were noted, but they were transient in all, and in the forty cases on record in which the magnesium sulphate has been administered in intraspinal injections apnea was observed only in one case, and it was brief and transient The *tendency to headache and pain in the limbs after the injection* can be reduced by a preliminary injection of morphin. *In future he intends to use an isotonic solution,* that is one with a freezing point at 0.56 below zero C He thinks that *this treatment may be found effectual also in major* chorea and in the chorea of pregnant women

61 Duration of Gestation (Wann tritt die Geburt ein? Die zufallig veranderte Dauer der Schwangerschaft) F Schatz

54. ***Influence of Ovaries on Development of Pelvis.***—Doria states that the average age at the first menstruation was 14 years and 3 months in 36,000 Italian women There seems to be a connection between the time of the first menstruation and the size and shape of the pelvis, a very early or very late onset of the menses having been found almost constantly in his 3,000 cases of malformation of the pelvis He believes that the facts observed confirm the assumption that the ovaries have an influence on the development of the skeleton and the nourishment of the bones, especially of the pelvis

This influence is unusually active during or just preceding puberty and consequently measures to insure rest and ample nourishment during this period with appropriate ovarian treatment will reduce the number of generally contracted pelves while the degree of malformation from infantile rachitis will be reduced to the minimum

57 **Absorbing Capacity of Vaginal and Uterine Mucosa.**—Higuchi found that the mucosa of the vagina was able to absorb potassium iodid, salicylic acid and strychnin either in a water, glycerin or cocoa butter vehicle The latter seemed to facilitate absorption most

58 **Chronic Endometritis**—Theilhaber became convinced five years ago from microscopic study of 120 uteri that the structure of the normal mucosa varies widely in different individuals even of the same age, and also in the same person at different ages Conditions are different also in the periods preceding and following menstruation He has since been conducting experimental anatomic and clinical research on the subject and asserts that treatment should be based on this fact Hypersecretion requires removal of the cause, iron for chlorosis, climatic hydrotherapeutic, psychic and dietetic measures for neurasthenia hysteria etc Cool sitz baths are useful in case of flabby uterus with or without ergot, and he also advises flushing the vagina with very hot fluids to stimulate the uterine muscle to contract He found cauterization of the interior of the uterus beneficial in some cases, applying a 30 per cent solution of zinc chlorid or formalin on a cotton swab Rinsing out the uterus does not seem to do much good in case of hypersecretion Local bloodletting is useful in case of hypersecretion from venous congestion By scarification of the vaginal portion, it is possible to withdraw several spoonfuls of blood several times a week Recurrence may be observed following sexual excesses or emotions—the latter as a factor in recurrences is not sufficiently heeded by physicians, as a rule, he says Vasomotor influencing of the vascular system of the uterus is responsible for the return of the hypersecretion in these cases He advises expectant treatment during the acute phase of gonorrheal endometritis In the chronic phase energetic measures are necessary Gonorrhea of the urethra seems to heal better on account of the constant flushing out with the urine, and the menstrual blood seems also to promote the healing of the uterine gonorrhea In the intervals between the menses pus stagnates in the uterus as the bend at the internal os interferes with the escape of the tenacious secretion The conditions are similar to those in an abscess in which there is not free outlet for the pus By rinsing out the uterus, large amounts of retained secretion are washed out, which otherwise prevent the healing of the process He treats such patients by periodical slight dilatation, using for the purpose a Schultze dilator every few days, and then rinsing out the uterus with a weak solution of some silver salt, or ichthyol in case the trouble is of long duration

59 **Treatment of Placenta Prævia**—Henkel comments on Futh's statistics of 618 cases of placenta prævia at Koblenz with a mortality of 143, that is 19 7 per cent Death was the result of hemorrhage in 98 cases and of puerperal infection in 31 Henkel declares that every patient with placenta prævia should be taken to some institution at once The general practitioner must tampon in case the cervical canal is not dilated, and he should not rely on "aseptic cotton," which is too often the source for infection, but should tampon with strips of gauze preferably impregnated with a 2 per cent solution of alum, but wrung out as dry as possible The vulva should be shaved first and the parts around disinfected The vagina is then rinsed out with some disinfecting fluid and then packed tight with the broad strips of gauze The bladder must be emptied before tamponing A patient thus tamponed with a T bandage to hold all in place can be safely taken to the nearest lying in hospital This treatment is applicable however only in case the amniotic sac is still intact and the cervix undilated In case the membranes are ruptured, he advocates version when the cervix is dilated enough to admit one finger He discusses the various points of this one finger technic remarking that skilful version and cautious management of the delivery are bound to give better results than have hitherto been realized In case vaginal Cesarean section is contemplated, he gives ergot at once so that its effect will be obtained simultaneously with the evacuation of the uterus He adds that the classical Cesarean section is seldom advisable for placenta prævia After the uterus is empty, if the hemorrhage still continues, he seizes the vaginal portion of the cervix with forceps and pulls the uterus down, forward and toward the right and then to the left This manipulation closes the uterine arteries more or less, both by direct compression of the vessels and by the traction

62 to 64 **Operations Under Intrapulmonary Positive Pressure**—Kuttner has the appliances both for the Sauerbruch negative pressure and the Brauer positive pressure technics, and has used them alternately in 21 operations on the thorax He describes this experience in detail, and states that both technics have their advantages, but that he prefers the Brauer method Danielsen reports from the same clinic considerable experimental work with both technics, including operative removal of a foreign body from a bronchus by direct bronchotomy He has found in the literature accounts of three cases in which this was done, reported by Curtis Duncan and Schiassi, with successful outcome in two cases He cites the various points to be borne in mind in such interventions and the best technic for resection of the lung The proximal sections of the bronchus can be separated from the lung without cutting, and without much hemorrhage The bronchus is best closed by a running suture including the cartilaginous bronchus and the peribronchial tissue Wounds in the lung are best closed with fine silk sutures taken through the pleura Dreyer and Spannaus report research on the physiologic phenomena during artificial maintenance of the intrapulmonary pressure the behavior of the respiration, and of the pulse in the general and lesser circulation, the blood pressure in the venous system, and the varying conditions in the thorax with each technic All this research confirms the fact that there is no essential difference between the action of the Sauerbruch pneumatic cabinet and Brauer's positive lung inflation

70 **Antiferment Treatment of Suppurating Processes**—The "physiologic treatment of wounds" introduced by Muller and Peiser was described in these columns June 6 1908 page 1930 It is based on the antagonistic action of proteolytic leucocyte ferment and its antiferment normally in the blood serum and, in increased amounts in morbid effusions If the antiferment is supplied artificially to a "hot" abscess it transforms the lesion into a "cold" abscess and thus it has unlimited therapeutic indications The antiferment can be derived from the patient's own blood serum after venesection or from puncture fluids If of foreign origin the serum is filtered through porcelain Trypsin has proved a convenient means of test

ing the proportion of antiferment in the serum. The antiferment acts only by direct contact, and the best technic for its application has been found to be by aspirating the contents of the abscess through a puncture, and then injecting the antiferment through the same needle, enough to fill the cavity without distending it. The contents of the abscess are then aspirated again, and again it is filled with fresh antiferment which is then left in the cavity. If the spot is still sensitive to pressure the next day, the procedure is repeated. No incision is required with this technic; it is applicable only when a mastitis or other process is tending to abscess formation. Thirteen typical cases of abscesses, *felons*, etc, are described in detail, out of an experience of 100 cases, to show the advantages of this "physiologic" treatment The antiferment attracted to the spot is probably, they think, the main factor in the benefit from *hyperemic treatment*. A serum rich in antiferment can be kept on ice for several weeks in stoppered vessels. It should be tested from time to time to determine its strength. The larger the proportion of antiferment, the better and longer the serum keeps

77. **Serodiagnosis of Staphylococcus Affections.**—Coenen has been experimenting with the cutaneous toxin test, agglutination, opsonic index and antitoxin tests, but found that the agglutination test—the technic similar to that in typhoid—is the most reliable of all. Positive findings are not obtained in recent, brief infection; a more chronic course is indispensable for positive agglutination.

78 **Duodenal Ulcer in Children.**—Kuttner found an ulcer in the duodenum in the cadaver of an infant a month old who had succumbed to intestinal hemorrhage. In a second case three round ulcers were found in the duodenum of a child of 4 dying with acute diarrhea and vomiting of blood He is inclined to believe that an ulcer in the duodenum may be a cause of stenosis of the pylorus in infants; the reflex spastic contraction of the pylorus may lead to functional stenosis This assumption is sustained by the fact that admixture of blood has been observed in the vomit in cases of stenosis of the pylorus, and even coffee dregs vomit. Another argument in favor of this assumption is the unusual amounts of free hydrochloric acid sometimes encountered with the stenosis Torday has reported a positive case in which an ulcer was found in the duodenum after death at the age of 8 months with the syndrome of congenital stenosis of the pylorus In obscure anemic conditions in infants and young children, the possibility of an ulcer in the duodenum should be borne in mind and the stool examined for occult blood. Treatment of ulcer in the duodenum should be along the same lines as for ulcer in the stomach If there is hemorrhage, hot cataplasms to the stomach region should be replaced by application of ice. Operative treatment has little chance of success during the shock from extensive hemorrhage

79. **Ultimate Results from Transplantation of Vessels and Organs.**—Capelle reports results from the experimental work in this line at Garré's clinic at Bonn The implanted arteries functionate well and the vascular wall adapts itself to the new conditions Veins taking the place of arteries become thicker and more like arteries It was found possible to restore the thyroid to its place and function by means of suture of the vessels after the organ had been totally separated and kept over an hour outside of the body. After its restoration to place the animals developed normally, but when the thyroid was finally removed for examination. 245 days after the first operation, the animals rapidly succumbed to typical post-thyroidectomy tetany. The experiences with circular union of transverse severed vessels and the substitution of resected arteries by implanted segments of arteries or veins, proved so successful that Capelle declares that the method is ripe for adoption in the clinic.

82 **Electric Treatment of Asthma.**—Gunzel is convinced that the asthmatic spasm is frequently traceable to some peripheral point In one case removal of a small projection in the nose completely cured nocturnal asthma in a boy of 5. Besides this class of cases, in 50 cases of bronchial àsthma he has applied the high-frequency current This current passed through an aching nerve renders it insensible, and it can be used to induce local anesthesia, to cure neuralgia, rheumatoid pains, etc In an acute attack of asthma the electricity rapidly *soothes and the spasm subsides From two to four* applications at one hour intervals relieve and cure the attack of asthma without necessity for morphin.

83 **"Thymus Death."**—In the two cases reported the apparently healthy children died suddenly during sleep and *nothing* could be found to explain the fatality except a very large thymus. Probably the child threw its head back in its sleep, thus compressing important organs between the large thymus and the spine. In both cases reported, the trachea and aorta were not involved; the compression was mainly on the veins as evidenced by the edema in brain and lungs and the striking coagulation in the pulmonary veins and left side of the heart.

85. **Sensibility to Pain on the Part of the Viscera Innervated by the Sympathetic.**—Goldscheider admits that the visceral nerves may be non-sensitive to pain when they are in a normal condition, but thinks that morbid conditions may arise in which they may become sensitive. The pain is a reaction the same as a reflex. It may be the sum of a number of sensations below the dignity of a pain, but becoming pain by their accumulation. This assumption is an argument against the existence of "pain nerves."

86. **New Pharmacologic Principle.**—Jacoby expatiates on the advantages of surgeons and pharmacologists working together, and describes experimental research which demonstrated that the joints are by no means the chosen seat of injected salicylic acid; the blood serum is normally its favorite stronghold. On the other hand, in animals injected with staphylococci, the salicylic acid was found in the joints in twice as large amounts as in normal joints. This led to the discovery that a drug obeys its own laws of distribution in the normal and diseased organism. This distribution may be different for each affection and individual case. He states that this simple law is a new principle which has been overlooked by pathologists and pharmacologists hitherto. It explains, for instance, how an infected joint can look out for itself and secure a concentration of the drug not reached elsewhere. It also explains how a sick person is able sometimes to stand doses which a healthy one would be unable to tolerate. In case of a joint affection, a large proportion of the salicylic acid administered goes to the joints, which in a healthy person would go to the central nervous system. The infected are thus less liable to intoxication than the healthy. This new principle also explains the phenomena of the "point of lesser resistance." Altered tissue has an altered power of attracting foreign substances, drugs or bacteria. Tuberculous tissue, for instance, attracts iodin more strongly than the normal tissues. If the eye of an animal is infected with tubercle bacilli, and iodin is then injected elsewhere, it will be refound almost entirely in the tuberculous eye. It is possible that this phenomenon may yet be utilized for diagnostic purposes. Velden has recently reported that injected iodin was not discovered in the sound parts of an organ, but it was found collected in the cancer foci in the organ. Jacoby calls the attention of surgeons to this fact in particular. Only in operations is the opportunity afforded to have an individual incorporate some drug and then to study the concentration of the drug in the tissues, the tumor or parts of the tumor. At present we do not know of any drugs that act especially on tumors, but advancing science may soon discover such. Examination of an excised scrap will then reveal whether the drug has reached the tumor, and whether it is best incorporated by way of the mouth or veins or subcutaneously or by direct injection into the tumor.

93. **Postoperative Gastrointestinal Hemorrhage.**—Schwalbach states that one-third of the cases of hemorrhage following operations on the appendix on record occurred in children. The hemorrhage is evidently, he thinks, the result of thrombosis in the vessels of the omentum and mesentery. Similar conditions can be reproduced in animals; the operation is the main factor in their occurrence. The prognosis is grave, and treatment can only be symptomatic. In the 30 cases on record, the outcome was fatal in 17. In the 2 personal cases reported, the hemorrhage followed an interval appendicectomy; the hemorrhagic stools were first noted the third and fifth day after the operation and they continued for a week, after which there were no further signs of hemorrhage. The first patient, a woman of 28, was treated with strychnin, opium and gelatin; the second, a man of 35, with adrenalin only. The hemorrhagic erosion in the cases that came to autopsy corresponded to the site of the ordinary round ulcer, and Schwalbach is confident that both are referable to local disturbances in the circulation, for which the operation is mainly responsible in the postoperative cases.

94. **Automobile Injuries.**—Zimmer states that 145 persons were killed and 2,419 injured by automobiles in Germany during eleven months in 1906-1907, and that 80 of the injured passed through Sonnenburg's surgical service at Berlin, with a mortality of 10. In one case a girl of 9 was run over by an electric cab and was dismissed from the hospital in good health sixty-four days afterward, entirely recovered from fracture of several ribs, of the upper arm and double fracture of the pelvis with laceration of the bladder. The almost immediate laparotomy allowed conditions to be promptly remedied, the arm placed in a splint and the pelvis in a plaster cast. The only disturbance left is that the right leg is still a trifle short. In 65 of the cases the injuries were very severe; bones were fractured in more than 50 per cent. Especially noticeable was the large number of fractures of the base of the skull and concussion of the brain, the extent of the hematomas and of the contusions of the soft parts and the undermining of the skin. Besides these, there were a few cases of the typical "automobile fracture," the lower end of the radius broken by too sudden starting of the lever when the spring fails to work. This injury generally heals rapidly. In one such case the diaphysis of the radius was fractured and the ulna dislocated to such an extent that it bored through the wrist.

95. **Tubal Pregnancy.**—Fiedler concludes from his research on 82 cases of tubal pregnancy that it is not so rare as some assume, but averages 2.3 per cent. of all pregnancies. A predisposition is afforded by gonorrheal and puerperal infection and by trauma. Elderly multiparæ formed the majority in his experience. He asserts that the presence of urobilin in the urine, in the absence of other affections predisposing to urobilinuria, is an important aid in diagnosing a disturbed extrauterine pregnancy. He advocates laparotomy, even if there is already an encapsulated retrouterine hematocele, and declares that it is not necessary to wait for the subsidence of shock. He advises removal of clots only in so far as it is possible to do so without injury of the intestines or prolongation of the operation.

100. **Ischemic Muscular Contracture and Plaster Casts.**—Hildebrand remarks that the denunciation of the plaster cast as responsible for the ischemic muscular contraction in cases of fracture of the elbow and forearm is irrational, as in 34 of the 56 cases on record no plaster dressing had been used, and as, further, the contracture had been observed before the advent of plaster casts. The trouble is the result of disturbance in the circulation of the parts, and it may occur from any disturbance of the kind. The radial and ulnar pulse should be carefully investigated in all such cases, and if the pulse is found weak no further compression should be permitted. If a plaster dressing or splint or adhesive plaster is used, the main point is to see that it is extensively padded. If the ischemic contracture then occurs, the primary injury of the vessel is the only factor responsible for the trouble.

101. **Prevention of Recurrence of Kidney Stones.**—Klemperer expatiates on the necessity for internal medical measures to prevent recurrence of kidney stones after their operative removal, and advocates for this measures to promote the flow of urine through the kidneys to wash out the sediment that otherwise might form concretions. Every such patient should be advised, he asserts, to drink frequently between meals, taking from 200 to 300 c.c. every two or three hours and to drink copiously just before retiring, as the night urine is the most concentrated and has the greatest tendency to sediment formation. A glass of water beside the bed at night can be sipped as the patient wakes—such persons are generally elderly and wake often. The fate of these patients depends on the observance of this advice. The kind of beverage is of less importance, although weakly alkaline, carbonated mineral waters should be given the preference. He adds that from the standpoint of prevention of recurrence of kidney stones, there are no contraindications to the use of alcoholic beverages. The patients with a tendency to obesity and heart disease should drink copiously, as above, but exclusively between meals, taking food frequently, but in small amounts, that leave the stomach soon empty, and drinking freely between the meals. In this way the tendency to kidney stones and to

obesity will be combated at the same time. Rosenfeld has his obese patients drink up to 10 quarts of water a day, all between meals, and has found this extremely effectual in reducing weight. In heart disease, the free ingestion of water as above is not advisable in case of failing compensation, but in other conditions it is not contraindicated. The intake of fluid within reasonable bounds does not injure the heart muscle, as is shown by the blood pressure and the experiences with diabetes. The diet should be mixed, but the oxalate-stone patients should refrain from tea and spinach, and the urate-stone patients from eating the glandular organs (thymus, liver, kidneys). He has known of instances in which a urate-stone patient had followed the physician's advice to refrain from meat, and this strict vegetarian diet for four years had resulted in the formation of oxalate stones in the kidney. Any exaggeration should, therefore, be avoided, although it is wise to restrict the amount of salt to the minimum needed to render the food palatable; the more salt in the urine, the greater the tendency to the depositing of sediment. Drugs are superfluous, he says, and even sodium bicarbonate should not be given unless the reaction of the urine is constantly supervised or harm may result. A weakly alkaline mineral water is perhaps best, but excess even of this should be avoided. In case of oxaluria, small doses of a magnesium salt (0.5 gm., or 7.5 grains, of magnesium sulphate four times a day) will keep the calcium oxalate in solution in the acid urine. Especial care is required in the cases of phosphate stones, as these display the greatest tendency to recurrence. Concomitant infection, of course, requires treatment, but the simple cases in which the urine is merely excessively alkaline, possibly the effect of a too exclusive vegetable diet, may require regulation of the diet and measures against hypersecretion in the stomach. It is a difficult matter to advise a patient whose phosphate stones are the result of gastrogenic alkalinuria. If lime is excluded from the diet, it is drawn from the tissues of the body and serious damage may result. No dietetic regulations are able to prevent recurrence of aseptic phosphate stones—all that can be done is to order copious drinking between meals, a mixed diet, supplemented by treatment of the nervous system and, possibly, occasional administration of sodium oxalate. In every such case careful analysis of the urine is imperative.

107. **Spinal Anesthesia.**—Bier regards cocain as the most dangerous and tropacocain as the safest drug for spinal anesthesia. The ordinary dose of the tropacocain is 0.05 gm. (¾ gr.), and the maximum dose 0.06 gm. (1 gr.). To this Bier adds 0.0001 gm. suprarenin; the solution must be isotonic and warm. The injection is made between the second and third, or first and second lumbar vertebræ, and the anesthetic should never be injected until the cerebrospinal fluid is flowing in a series of rapid drops from the needle. Bier states that the only serious by-effect observed was vomiting in about 5 per cent. of the cases. In the last 400 cases the only noticeable symptom was transient pallor and small pulse; the latter condition being observed once in a man of 82. Headache occurred afterward in 6 per cent. of the cases, but generally in women who had suffered from headache previously. Recently, he has been using with satisfaction the scopolamin-morphin technic as a preliminary to the spinal anesthesia, especially for nervous and excited patients. He makes two injections, an hour and a half and three quarters of an hour before the operation, of a mixture of 0.0012 gm. (1/50 grain) scopolamin and 0.03 gm. (½ gr.) morphin with distilled water to 2 c.c. injecting 0.7 or 0.8 c.c. at a time, thus using only about two-thirds of the total amount of the mixture. With this technic the patient is not too drowsy to sit up for the spinal puncture, but he must be supported or he will fall as he sits, bent forward, on the edge of the operating table. Bier's experiences with a gelatin addition to the anesthetic and with attempts to extend the analgesia have not been successful. In conclusion he reiterates his belief that the evil effects of general anesthesia are much more extensive and serious than is recognized at present. The general anesthesia causes important disturbances which it is impossible to set down in statistics. This is shown, he says, by the patients operated on for cancer of the rectum under general anesthesia—they present afterward the picture of serious depression, while those operated on under spinal anesthesia do not seem sick at all afterward. The same is observed after the Freund-Wertheim operation on the uterus. Bier has had two fatalities with spinal anesthesia. One was reported by Dönitz in 1906; more than twice the standard dose was injected in this case. The second, unreported case, was that of a man of 40 being treated for external inguinal hernia. The standard dose was given, but without any suprarenal preparation, and the pelvis was raised as usual. Vomiting and sudden heart failure followed in a few minutes.

108. **Spinal Anesthesia.**—Oelsner and Kroner report the experiences at Sonnenburg's clinic and the results of considerable experimental research. They experimented with injection of salt solution cooled to freezing point, after withdrawal of a corresponding amount of cerebrospinal fluid. The ice-cold fluid does not injure the tissues while the anesthetic effect justifies, they say, further trials of this method, especially, they add in conclusion, as none of the methods of spinal anesthesia in vogue to date are entirely free from possible evil effects and never can be free from them, as they are based on the introduction of a foreign chemical substance which must inevitably do more or less injury.

113. **Attempts to Resuscitate Animals by Passing Arterial Blood Through the Heart and Nervous System.**—Zeller's article reviews the numerous researches of others in approximate lines and reports a series of experiments with various substances to act on the blood. The results suggest that the method might possibly be applied in the clinic as a last resort.

Medizinische Klinik, Berlin.

114. **Treatment of Anthrax.**—Barlach states that under expectant treatment 3 died out of 10 patients with anthrax, while none died in the 9 cases between 1900 and 1905 in which active treatment was undertaken. Since 1905 he has been using a method that seems to shorten the course of the affection still more, and there has been no mortality in the 23 cases and no disfiguring scars. The first principle in treatment is to avoid further injury. Especially injurious is any pressure on the pustule, which forces the bacilli out into the blood. It is important, therefore, for the patient to lie quietly in bed. In mild cases it is sufficient to cover the pustule and its vicinity with an antiseptic moist dressing; mercury bichlorid or aluminum acetate can be used for the purpose. The strictly local lesion rapidly heals under this treatment, but in the severer cases a crucial incision is made and the actual cautery is used to make a groove of deep punctures around the lesion. This groove forms a scab which renders it difficult for the anthrax bacilli to penetrate into the surrounding tissues. This crucial incision and the ring of cauterization around the lesion are simple and can scarcely be considered an actual operation. The pain is so slight that it seems to indicate that the sensibility in the pustule is much reduced. He adds that the effect of this treatment is invariably so good that it has scarcely a parallel in therapeutics, except antitoxin in diphtheria.

115. **Mitral Stenosis and Relative Insufficiency of the Pulmonary Valves with Mitral Stenosis.**—Ortner concludes this extensive study of the auscultation findings in three cases of mitral stenosis, with a review of a number from the literature. He believes that the distinctly different character of two murmurs of the same phase of contraction of the heart does not necessarily imply a different origin for the murmurs. In certain cases the whole series of auscultation symptoms (presystolic murmur, accentuated first sound, systolic and diastolic sounds) of mitral stenosis and incompetency is audi-

ble not only over the left base of the heart, but it is conveyed up into and is audible in both carotids. In rare cases of mitral incompetency the systolic murmur may be heard exclusively in the left chest at the back, in the region of the angle of the scapula, at least for a certain length of time. The possible existence of relative incompetency of the pulmonary valves *in consequence of mitral stenosis* is rendered probable by Bryant's first case, but it is not proved. All the rest of the cases classified under this head were in reality cases of mitral stenosis with a diastolic murmur over the left base of the heart.

128 Etiology [illegible] (Aetiologie der Köhlerschen Knochenerkrankung.) A. Dobisch.

119. Research on Variola.—This communication from Rio de Janeiro reports research which seems to indicate that the *causal agent of smallpox is a symbiosis with a streptococcus,* plus the presence of a certain complement. The scarcity of the virus in the circulation and the lack of antibodies in the blood seem to demonstrate that smallpox is predominantly an ectodermal affection of the tissues, and that the immunity is an immunization of the skin.

120. Influence of "Scarlet Oil" on Mouse Tumors.—Werner has been experimenting with the dye, scarlet red (*Scharlachrot*) oil injected into a mouse tumor. The findings show that the resulting proliferation is not from chemotactic influencing of the cells, but is the result of their irritation. The proliferation in the mouse tumor described occurred always away from the injected fluid. This concentric growth is the first testimony that the cells are not attracted to the dye, but can grow away from it.

121. *Nervous Disturbances in the Arms in Arteriosclerosis.*—Wandel found dyskinesia and paresthesia in 13 out of 30 women over 55 years old, and in 6 others there were more or less pronounced arteriosclerotic disturbances in the legs. Similar disturbances were noted in 13 out of 32 men. In all these patients the peripheral vascular disturbance accompanied arteriosclerosis, but no general taint was evident in any of the cases, no syphilis, diabetes or tobacco poisoning. Only the *age over 55, with its general and special phenomena of wearing out,* was common to all the cases. There was no neuropathic tendency, but the localization of the peripheral disturbances seemed to be always determined by the functional demands made on the extremities. Local chilling and exposure to cold water or other local injury seemed to entail the *trouble, with* their excessive reflex irritation of the peripheral vessels, in addition to the functional demands, reducing the vitality of the *parts and localizing the arteriosclerosis.* Aschoff found that typical arteriosclerosis could be artificially induced by hanging up an animal by the hind legs for three minutes once a day. The analogy was complete to the microscopic details. The peripheral occupation-arteriosclerosis shows less tendency to calcification and changes in the media than to obliterating endarteritis with its consequent interference with the nourishment and functioning of the peripheral nerves.

126. Foreign Bodies in the Esophagus.—Ach relates his experience in seven cases of swallowed foreign bodies extracted with the aid of an esophagoscope; *three additional* cases required esophagotomy. He expatiates on the advantages of *esophagoscopy as facilitating* the removal of foreign bodies. It is the safest, simplest and least dangerous method for diagnosis and treatment in such cases. Even the Roentgen rays may give misleading findings, as in a case described in which a patch of calcification simulated a foreign body and led to extreme efforts, to dislodge it, in the course of which the foreign body was expelled from the bowels. He relates a few cases in which numerous foreign bodies passed harmlessly through the digestive tract. In one, a man swallowed nails, needles and various foreign bodies and passed a large number by the rectum with little disturbance, one such evacuation including 16 nails, 3 hairpins and a pocket knife, beside removal of hatpins, etc., *in the course of three laparotomies.* Ach warns against the practice of pushing a foreign body down into the stomach unless it is known to be a small coin or a soft piece of meat or bread. The local spasm of the muscle holding the foreign body in the esophagus can sometimes be *relieved by general anesthesia.*

132 *Resuscitation in Apparent Death by Means of Oxygen and Intubation. (Wiederbelebung Erstickter und Scheintoter mittels Sauerstoff und Intubation.) F. Kuhn.

129. *Hydrochloric Acid* in Therapeutics.—Fuld reviews the various theories in regard to the secretion of hydrochloric acid and its use in therapeutics, and calls attention to a number of erroneous conceptions in regard to treatment of stomach trouble. Among them is the administration of pepsin in an alcoholic medium, as alcohol is a ferment poison. He presents arguments to show that a small amount of hydrochloric acid before meals answers best the desired therapeutic purpose. The hydrochloric acid is very useful in a large proportion of cases of deficient secretion; those without symptoms do not require any treatment, and the severer cases can not be influenced by hydrochloric acid alone. He gives from five to ten drops of dilute hydrochloric acid several times a day. *This small amount has little direct influence on the digestion,* but it stimulates by reflex action the entire digestive process and approximates the physiologic antiseptic and antitoxic action, while it stimulates the secretion of pancreatic juice. In regard to pepsin, he suggests that it might be simpler, cheaper and the results more complete if the *pepsin digestion* were done before the food is taken. Combination of hydrochloric acid with pepsin or other substances is liable to annul the action of the acid completely. Food for persons with deficient secretion of hydrochloric acid requires more careful preparation or possibly pepsin predigestion.

130. Differentiation and Internal Treatment of Stenosis of the Pylorus in Infants.—Ibrahim enumerates the differential points and outlines the internal treatment, which has proved extremely successful in his hands in fifteen cases. Experience has shown that the hypertrophy of the pylorus increases and recedes, and influences can be brought to bear to favor its relaxation. During life the stenosis is by no means the hard *ring found in the cadaver,* and everything shows that the hypertrophy can be reduced by appropriate measures. The chief aim is the neutralizing of the acid stomach content with a mild alkaline water with the milk or between the meals. The act of sucking the breast induces a predisposition to spasmodic contraction of the pylorus, so that he *finds it* advisable to draw the breast milk with a modern breast pump and feed it to the child with a spoon, possibly removing the fat. The breast secretion can be kept up for two or three weeks in this way. Very small amounts of the milk, ice cold or merely at room temperature, are less liable to induce vomiting. He reduces the feeding to 30 gm. (a little less than an ounce) every two hours, or one-third this amount every hour, day and night, with possibly tepid Vichy water between meals in the same amount. This strict dieting should not be kept up for more than 8 or 10 days without supplementing it with rectal nutrient enemas. The stomach should be rinsed out every day and a cataplasm applied to the region of the pylorus to reduce the pain and favor the relaxing of the spastic stenosis. In severer cases he has these cataplasms applied immediately after the meals, every 4 hours, day and night, for several weeks, removing the cataplasm as soon as it cools. Pfaundler recommends for the same purpose a Japanese pocket stove. With these measures *complete recovery is the rule, and the stenosis never recurs,* although nervous disturbances may be observed in later life. This fact suggests that such children require special oversight for prophylaxis. The differentiation of this form of stenosis is not difficult. The symptoms seldom develop before the end of the first or during the second, third or fourth week or even not till the eighth week. The first sign is frequent vomiting and decline in weight with the absence of intestinal dyspepsia. There is generally constipation and the stools are dark brown or a light meconium. The inefficacy of ordinary measures to control the vomiting and the explosive character of the latter, the absence of bile in the vomit, the pain during drinking and the extreme hunger of the infant, all aid in the differentiation, confirmed by the violence of the peristalsis in the stomach and the discovery of the tumor formed by the enlarged pylorus. Only 45 per cent. have been saved to date out of the 138 children operated on for this trouble, but if the symptoms continue to progress, operative treatment should be considered after 8 or 14 days, not waiting until the child has become too debilitated to stand any operative intervention.

132. **Oxygen by Intubation for Resuscitation in Apparent Death.**—Kuhn urges that a double current tube—such as he uses for peroral intubation—should be an indispensable adjunct to the life-saving equipment. The tube should be used to supply oxygen to the lungs, especially when the measures for resuscitation have to be kept up for hours. It avoids the injury of the parts liable with other measures, while it insures an even supply of air or oxygen, with its regular evacuation.

138 Hypoplasia of the Tubes in Relation to Extrauterine Pregnancy. O. Höhne.

133. **Metastasis of Uterine Carcinoma in Nervous System and Organs of Sense.**—Offergeld has found records of metastasis in the brain in 20 cases; the metastasis generally occurs early, while the uterine cancer is still operable, and the metastatic nodule is solitary, although daughter tumors in the lungs and liver are comparatively frequent. The brain metastasis generally causes no symptoms; especially noticeable is the lack of signs of pressure on the brain. In 3 of the cases on record there was right hemiplegia, and in 3 others vague symptoms suggesting merely a possibility of an organic brain affection. He urges that the brain should be examined in all cases of uterine cancer that come to autopsy. In 5 cases on record metastases in the dura were observed, generally multiple, and accompanying advanced cancer. He was unable to find any record of any metastasis in the spinal cord, but asserts that the peripheral nerves in the vicinity of the uterine cancer are involved in metastasis more often than is generally supposed. Scraps of the nerves should be excised for histologic examination to throw further light on this subject. He has collected 4 cases of metastasis in the eye and 1 in the tongue. In all the cases in which the nerve was involved, the axis cylinder was intact, the connective tissue being exclusively affected.

140 *Simple Apparatus for Artificial Respiration When the Thorax Has Been Opened. (Einfacher Apparat zur künstlichen Atmung bei eröffnetem Thorax.) M. Katzenstein.

140. **Apparatus for Artificial Respiration when the Pleura is Opened.**—One of Kuhn's peroral tubes is introduced into the trachea, the outer end connected by a long tube with a small bellows. A second tube branches from the center of the long tube with a funnel at the end through which the anesthetic is administered. When the thorax is opened the lung collapses, but it is inflated again by the bellows. The air then escapes through a small valve in the long tube, after which the lung is again inflated with the bellows. This is kept up at rhythmical intervals, and respiration proceeds smoothly and regularly. Katzenstein has used this apparatus once in the clinic and with complete success, after extensive trials on the cadaver.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a *full equivalent to those sending* them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

YELLOW FEVER AND THE MOSQUITO.*

J. H. WHITE, M.D.
Surgeon, U. S. Public Health and Marine-Hospital Service.
NEW ORLEANS.

From LeBeuf's historical notes on the subject we find that, appearing at Boston in 1798, at New York in 1789, at Philadelphia in 1699, at Baltimore in 1819, at New Orleans in 1701, and at many other points along the coast, and spreading to our interior, low-lying towns, yellow fever carried death and terror far and wide.

Considered at first a visitation of Providence, it was simply submitted to and all efforts were directed solely toward healing the sick. Considered later as a possibly preventable malady, it was combated by fumigation of all sorts, but with no apparent result; and finally that abomination of desolation, the quarantine of non-intercourse, was set up, doing far more damage than good. While checking perhaps in some slight measure of doubtful value the spread of the disease, it checked fatally the life-giving stream of commerce all through the south, while business went freely on in the north, which had meanwhile, during the first half of the nineteenth century, succeeded—as the accidental result of municipal improvements such as paving, drainage and water supply—in ridding itself of this almost perennial unwelcome visitor.

Who can say what untold millions are represented in the annihilated commerce of the southern tier of states as a direct result of epidemics, or what other millions represent the indirect loss in permanent commercial relations which found their best interest most naturally in our northern ports when all the south barred its doors for six months in every twelve?

Following as a perfectly rational sequel to the hideous barbarity of land quarantines since our Civil War, we find nearly all communities trying to conceal the existence of the first few cases of yellow fever. Their misfortunes having been punished as though crimes, what was more natural than that they should conceal those misfortunes even as a criminal would his misdeeds, hoping to keep them concealed until frost should come to their relief?

Pertinent to this discussion is another fact, namely, that many of the concealments just mentioned were undoubtedly the result of honest error in mistaking for malaria on the one hand and dengue on the other the first few cases of yellow fever; for let no man imagine that diagnosis is always easy in such cases. It may be that a few men like H. R. Carter and John Guiteras may diagnose all cases with unerring precision, but many there be who, even in the presence of a known outbreak, fail to recognize a mild case, and many more who, without knowledge of existing cases to put them on their guard, fail utterly to recognize a virulent type of yellow fever as anything more than a vicious malaria.

Again, a source of error on the other side of the account has been the mistaking of Dakar or Chagres fever at quarantine stations for possible yellow fever, and many ships have been held for days pending a decisive conclusion.

The errors made between dengue and yellow fever are so innumerable on both sides as hardly to need mentioning, and to-day, despite all our knowledge of the means of transmission and of the safety with which yellow fever can be handled, you have only to announce dengue in a southern city to have all the rest propose to quarantine that city and be in an agony of anxiety while investigations are made and the identity of the disease established.

It may be said that such confusion will do no harm, since we have learned how to take care of yellow fever; but it does infinite harm to the unfortunate yellow fever patient who, at the risk of his life, is freely dosed with quinin, or to the equally unfortunate Chagres patient who, needing quinin in heroic doses, gets Vichy and cracked ice, while the unfortunate community with a suspect within its gates gets a body blow to its business interests from which it takes a year to recover.

How can these confusions be avoided? The answer is simple—destroy all stegomyiæ, all anopheles, all culices. This we can do, must do, and will do, just so soon as public opinion takes full cognizance of the truth and acts on it—not sooner, for be assured that laws and regulations without public approval are "as sounding brass or a tinkling cymbal."

Theoretically, this elimination is an easy matter, since, through the splendid work of such men as Theobald, Howard and Giles, we are informed on every phase of mosquito life, but practically it calls for an infinity of detail and almost superhuman patience and perseverance.

Let us consider, first, the temporary amelioration of conditions arising from infection of the *Stegomyia calopus* and the *Culex pungens*, both practically domestic animals.

Assuming that we have a stegomyia infection in our community, we have to deal with two phases of the question: first, the isolation of all patients from any further possibility of being bitten; and, second, the destruction of all mosquitoes which may by the minutest chance have bitten the patient during the first three days of his illness, bearing in mind that we are now trying to kill possibly infected mosquitoes only and that the death of any others is merely incidental.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

We place a mosquito bar with eighteen meshes to the inch around our patient, screen every door and window opening into his room with the same mesh, close the fireplace with cloth or cover the top of the chimney with netting. We treat the whole house in this same fashion, and can then feel that the danger is confined and that we may proceed at our leisure to destroy the mosquitoes, having a fair margin of time before the infection in the insect becomes potential for harm to man—ten to twelve days. If need be, we can wait until the recovery of the patient, though it is better, if circumstances permit, to kill all insects in the rest of the house after the third day; then remove the patient quietly to a clean room and kill those in his room.

Many things have been suggested, but for absolute efficiency nothing save cyanid equals sulphur dioxid in 2 per cent. volume applied after everything in the room is opened up so as to uncover any hiding place, and the cracks in doors, windows and other places are carefully pasted over.

The sulphur dioxid gas should be applied in 2 per cent. volume for not less than two hours, though, according to Francis, in the hands of a skilful man 1 per cent. for four hours will do equally well and do minimal harm to dyes and fabrics.

If other houses are very close at hand, and especially if they have coincident windows and doors in close juxtaposition to the infected house, it is our custom to fumigate such houses also, though it is exceedingly doubtful if the infected stegomyia travels any distance. Where she finds shade, blood, moisture and a place to lay her eggs she wants little more.

A severe test of this unlikelihood of her traveling was made in 1905. The Louisville and Nashville trains leaving the city of New Orleans passed directly in front of the original infected area around the French Market, then down Elysian Fields Street for a mile, with rampant infection on both sides of the street, and went their way to the Alabama line, 116 miles distant. For about ninety miles through Mississippi they were occupied by guardsmen of the Mississippi National Guard, who acted as train inspectors and occupied the coaches with the passengers on these trains, going back and forth day and night, rain or shine, between the Alabama line and New Orleans, the same coaches always being used and nothing done to kill mosquitoes in them because those mosquitoes were not believed infected—which surely they were not, as not a single case of fever of any sort developed on those trains or among those guards. If the infected stegomyia travels, surely some must have gone aboard.

These facts are simply stated to show the uselessness of fumigating a wide district when we know our focus to be definitely located in one house.

The rules for killing *S. callopus* apply to the *C. pungens*, which in a lesser degree has become, like the former, a domestic animal. It is, however, necessary in this case to fumigate immediately and to move the patient as soon as a room is prepared and to continue the screening till the patient recovers from the dengue, since we are not assured of any well-defined infective period, as in the case of yellow fever. Graham continued protection in Beyrout ten days after recovery. Always fumigate near-by houses if possible, since this insect undoubtedly drifts further than the stegomyia.

Lastly, in this matter of partial eradication, we would in the case of anopheles infection fumigate exactly as before, except that there would be need to apply our screens until well after nightfall so as to catch the anopheles, which, for the most part, spends her day in the shrubbery or grass outside and only becomes sociable at nightfall, our procedure otherwise being the same.

It should always be borne in mind that the mosquito is a very small insect, capable of pushing into small cracks and under the impetus of sulphur dioxid likely to go as naturally to any opening accidentally left uncovered as water will to a leak in a jar. Therefore, cover the chimneys, paste paper over all cracks, search the windows and don't pull down the glass and leave a half-dozen able-bodied infectors between the glass and an outside wire screen to make you sick at heart some days later by producing another case of fever. Above all else in taking hold of an infected house, don't stir up things in the rooms, but go about the screening and pasting gently, softly. Don't drive your mosquitoes out; keep them in to kill them. Many zealous disinfectors have made this fatal mistake.

If circumstances will not permit the temporary screening of the chimney-top, then, on a bright sunny day if possible, soak a few papers in kerosene and stuff up the chimney and fire immediately, afterward pasting up the front of the fireplace before fumigating.

Perhaps these details are tiresome—so be it, but they are as necessary as asepsis is to surgery. They are the meat of the whole matter, and no effective work can be done without them.

For the permanent and complete elimination of all mosquitoes we must first acquaint ourselves with their habits and their habitats as well as the ways and means of destruction. The subjoined facts are gathered from the splendid work of Col. W. C. Gorgas, my brother officer Surgeon H. R. Carter, and Prof. John Guiteras and the writings of Dr. L. O. Howard, together with my personal observations and experiences in dealing with epidemic conditions.

The stegomyia breeds in dirty water only when she can not find clean water, and being a very delicate insect and exceedingly sensitive to hot sunshine, she requires that her breeding tank shall be still and dark. She will not use a natural pool for oviposition, but chooses artificial water-containers. Even when forced to the gutter for lack of a better breeding-ground, she seeks the gutter with sides and bottom of stone or wood. I know of no authentic case on record of any eggs found in natural pools. The place of election with her is the cistern; then the water-barrel, tub, bucket, shady and sagging points of roof gutters, old bottles under the bushes in the yard or under the edge of the house, old oyster and tomato cans, the fonts and vases in cemeteries, the church fonts occasionally, and in houses closed up in summer the bowl of the water closet, the traps of the plumbing generally, water left in pitchers, spittoons, etc., and, as reported by von Ezdorf, in the water partition of a small glue-pot—in fact, any clean or reasonably clean water. Failing this, she will use a dirty spittoon or even a cesspool, but not muddy water. She leaves the spot where she is born just as soon as she can fly and preempts quarters with the nearest human family, and there she lives indoors, like any other domestic animal, only paying an occasional visit to the nearest water-container to deposit her eggs. Except when taking residence at birth in a passenger coach, it is doubtful if she ever does anything in the way of migration, and it is practically certain that this is the limit of her travels after fecundation. According to Howard, she has, to a far greater degree than any other mosquito, learned man's ways, and hence is far harder to capture or kill than even the male of her own species. She not only lays her eggs all summer long, but also lays in October some batches to hatch in April, and herein lies much trouble.

The *Culex pungens* breeds in the identical situations chosen by the first-named variety, and, in addition, also breeds indiscriminately in any kind of water which may be available, either in gutters or natural pools, travels more between house and open air than her more domesticated cousin, and is easier to kill or take alive. Put a dozen of these insects with three or four stegomyiæ in a glass jar and you can readily capture the culices and will probably succeed in getting all of them cupped before you catch one single stegomyia, these latter seeming instinctively to get at the back of your hand just as, in freedom, they approach by choice the back of your neck or under your trousers, seldom making a frontal attack.

The three anopheles with which we have to contend in the United States, and whose habits have been so fully covered by Colonel Gorgas, all prefer a swampy breeding-place and will choose stagnant scum-covered water under the shade of trees and shrubbery if given a chance to do so. From this starting point they migrate, after hatching, to some clump of dank grass or shrubbery near a house, and from this point of vantage enter the house after nightfall in search of blood. They do not fly very high, and this fact gave ground for the old idea that houses built high were safer in malarial countries because noxious miasms kept close to the earth. It has been said that the second stories of the old days were practically exempt from malaria and the third entirely so. Be this as it may, personal experience has shown anopheles vastly more numerous on the ground floor than on that above.

Summing up all these facts, then, with the further fact that we intend to exterminate all kinds of mosquitoes, it is a natural corollary that we must destroy all breeding grounds of every sort. We should drain all pools absolutely and avoid leaving pockets in our ditches, or, should this be impossible, place cans of oil, according to Colonel Gorgas' method, about three feet above the water, dropping twenty drops per minute on the surface; or we can float on the surface of pools a few billets of soft wood soaked in petroleum, which will give off the oil little by little for a considerable period and make our oiling last longer than if simply applied to the water direct. For swampy pools covering considerable ground the crude oil is good enough. In the cases of pools which must be kept for watering cattle the edges must be made clean and sharp to avoid grass and weeds as a hiding place and the pool stocked with stickle-back minnows, which will destroy the larvæ and pupæ very effectively in clean-edged ponds, thus obviating the necessity for any other action. The new larvacide mentioned by Colonel Gorgas will supersede very much of this.

All undergrowth of every sort must be cleaned away around such pools as must remain, as well as from drained ground, and the sun must be allowed to give us its tremendous assistance as a dryer, for no mosquito seeks a bald and sunny spot as a breeding-ground.

While the drainage is in progress it is well to clear a wide stretch, 200 yards, of ground around houses subject to infection, thus destroying the daytime lurking ground of the anopheles. All street gutters should be carefully graded, furnished with smooth, hard bottoms, and sides kept cleaned so that they never can contain any save running water.

All roof gutters should have a gentle grade and be so firmly built as never to sag. Cheap construction should be forbidden by law.

All cisterns must be covered absolutely by either solid or screen material, and both inlet and outlet screened. We can not be too careful of our cisterns, since these, as before said, are the chief breeding ground of stegomyiæ and should be abolished wherever possible.

Barrels, tubs, buckets, pans, etc., must be emptied and scrubbed at frequent intervals, under penalty of their being forbidden. Simple emptying does no good whatever, as eggs and larvæ cling to the wood. All places in, under and around the house, every inch of the premises, must be rigorously policed in order that no chance containers may remain.

Public places—like churches, cemeteries, etc.—and business houses of all sorts, as well as factories and wharves, must be watched unceasingly, for churches and cemeteries may have neglected fonts, and business houses do have cisterns, old cans and broken bottles, and these are more apt to go unnoticed than such things around residences.

In the late fall the insect deposits eggs which, according to Dupré of Baton Rouge, remain in the water all winter until it becomes warm enough in the spring to hatch them, or if the water in an old tub, for instance, dries out, the eggs cling to the sides and bottom, and if that tub is filled in spring or summer time the larvæ appear in due season. This is probably the manner in which the stegomyiæ survive the winter in myriads, and the lesson therefrom is obvious: to make a vigorous war on the insect in late summer and autumn and to push the policing rules to absolute perfection at about the time of the first frost. We must not underrate our enemy, and to make effective war on mosquitoes we must have as inspectors thoroughly trained men, patient, sharp-sighted and persistent, with minds alert and capable of individual initiative. Such men can not be recruited from the ranks of the political "boys" around our cities. We must have men who have developed what Colonel Gorgas has happily termed an "automatic mosquito scent"—who become, because they love their work, so skilled that they recognize mosquito breeding ground by the same subconscious processes through which the sportsman instinctively knows where to seek game, and who "recognizes the varieties by flight, attack and resting form."

Because of possibly confused diagnosis every case of malaria should be traced to its origin as carefully as every case of yellow fever.

The history of every civilized community has demonstrated that advancing civilization ordinarily will destroy anopheles but only fosters the growth of *Stegomyia callopus,* just as it does mice and roaches, except when that civilization is of such an exacting sort as will have none but the best of everything.

We must, therefore, push forward, in addition to our specific fight on mosquitoes, the broader measures which shall render that fight a permanent victory. We need to drain every foot of our marshes and so destroy malaria both in country and in town. All the habitats of man must be so clean and dry that no breeding-ground will be found anywhere for the pestilential mosquito. Many southern cities have taken up this work and all, doubtless, will in time.

It would be folly to say that the work done in New Orleans is perfect, but I take a real pleasure in saying that the persistent efforts of the New Orleans City Board of Health for the last three years in maintaining the screening of cisterns and other water-containers, pending a good water supply and the concomitant necessities of paving and sewerage soon to be finished, has borne fruit in a greatly reduced stegomyia population. To the patient work in this direction of Dr. O'Reilly and his predecessor, Dr. Kohnke, all honor is due.

Broadly speaking, however, what we have as yet done to prevent yellow fever is little, save to quarantine our borders, a performance which, looked at logically, is on a parity with shutting up all honest people to protect them from thieves instead of eliminating the thieves. Granted that we must do this for the present—and it is beyond question necessary to do it until better measures are inaugurated—it is effective only as far as our coasts are concerned and does not, can not, give absolute safety on our land borders. Our seacoasts are protected by the most efficient maritime quarantine service on earth, but it is only a question of months when railway communication will be complete from Central America to the United States. It is complete now from our border down to Huixtla, in the state of Chiapas, Mexico, and a passenger can come from Huixtla to New Orleans in six days. One more day of railway travel will allow that passenger to come from San Salvador, and when the schedules get down to American standards and eliminate night stops, as they will in a short time after getting into good running order, one can travel from Salvador to New Orleans inside the incubative period of yellow fever, and can reach Texas well inside that period.

Now, let us assume that the border is watched either by our undoubtedly able and honest neighbor, Dr. Liceaga, or by ourselves, who shall say that a passenger may not cross the border on foot into Mexico from Guatemala or into our country from Mexico and take train as a local passenger? How can this be prevented? It would take the whole army to guard our Mexican border.

These means of ingress are constantly enlarging, nor must we forget that which every experienced sanitarian knows, namely, that the unsuspected point is the one that threatens us most. If we are watching a tropic port in full belief that yellow fever is there, I may safely say that port will never infect us; but if we sleep over our danger and believe nothing to exist, then, indeed, are we running a fearful risk. So long as one nidus of *Stegomyia callopus* exists in the tropics, so long must every person from that point be observed for six full days, as we do now observe them, utterly regardless of a clean bill of health; not detain them, mark you, but observe them; and all irresponsible people should be either barred or detained so long as we must still use quarantine as a weapon of defense.

As matters now stand, one of our best safeguards, and that a weak one, lies in the homely axiom of Carter, that "when a place has yellow fever to give away, it has a plenty." In other words, we are generally aware, though not always, of an outbreak in time to guard against it. But this applies to sea quarantine only and not to land work. In 1897 Montgomery, as her health officer humorously put it, "bottled up a dozen cases inside herself" when she quarantined Ocean Springs, and in 1905 Vicksburg and many minor towns did the same. These and other instances, some showing that infection undoubtedly went through the lines of a *cordon sanitaire* so strong that no community could possibly maintain it except in times of dire need, all tend to show that land quarantine is and always will be a broken reed to lean on and that in its last analysis the only rational preventive of yellow fever is sanitation, not quarantine.

I claim no originality in this statement.

On Dec. 4, 1895, Surgeon-General Wyman wrote a vigorous protest to the Secretary of the Treasury against the sanitary condition of the island of Cuba, bringing out strongly the very point here named, that the true solution of the question is sanitation rather than quarantine, which protest, but for the presence of a revolution in Cuba, would doubtless have borne fruit.

Following this, in September, 1896, the American Public Health Association adopted resolutions to the following effect: "First, it is the duty of every government possessing seaports thus infected to institute engineering and such other sanitary measures as will remove this menace to the seaports of other nations. Second, it is the duty of all governments threatened with an invasion of yellow fever from a seaport in which the disease is allowed to persist to make such representations to the government in possession of the threatening seaport as will induce it to adopt the sanitary measures necessary. . . . "

Again, in framing a plan of action for the International Conference of American States the Surgeon General called attention to the necessity of concentrating effort on "the one disease which jeopardizes the safety of 25,000,000 people, . . . imposes restraint on commerce, causes occasional depopulation of cities and financial distress or ruin," and particularly referring to Cuba, quoted from the report of the National Board of Health for 1880, in which Cuba is characterized as "disseminating, annually to other lands as from a central hell, disease and death."

Thus, years ago, he invited attention to the necessity for sanitation as the real remedy, and, by inference, to the fact that quarantine is only a temporary expedient.

Finally, then, what we must do and surely will do when our people awake, is:

1. Destroy within our own borders all disease-bearing mosquitoes.
2. Follow the advice of Surgeon-General Wyman given in 1895 in his letter to the Secretary of the Treasury strongly urging that Havana and all other then existing danger points be compelled to clean themselves.
3. Educate all our young physicians as profoundly as we can in entomology and in tropical medicine, remembering that it is no small part of the duty of the physician to educate his people in sanitation. The blind may not lead the blind.

No profession exerts a stronger influence over the people than ours, and we can not shirk this duty, which is plainly ours, and though not heralded so far and wide as the modern crusade against the great white plague, this crusade we invoke against the mosquito is fraught with equal import to our race, for when it can be said that the twin curses of the south, malaria and yellow fever, are no more, it can with equal truth be said that the physical stamina needed to fight phthisis has been increased by 50 per cent. If I may see the accomplishment of this, I will gladly paraphrase the words of the prohpet of old, and say, "Lord, now lettest Thou Thy servant depart in peace, for mine eyes have seen Thy salvation."

MOSQUITO DESTRUCTION IN THE TROPICS.

OCCURRENCE AND HABITS OF ANOPHELES; BREEDING-PLACES; METHODS OF DESTRUCTION; CONDITIONS THAT FAVOR ANOPHELES PROPAGATION; RESULTS OF ANTIMALARIAL WORK.*

J. A. LE PRINCE, C.E., A.M.
Chief Sanitary Inspector Isthmian Canal Commission.
ANCON, C. Z.

In preparing these notes it was originally intended to indicate briefly the methods of procedure in mosquito destruction during the antimalarial campaigns near Havana and on the Isthmus, as well as the stegomyia destruction work. It was later thought that a bare outline covering the more important part of such operations would be rather long. Therefore, the subject has been limited to the antimalarial campaign on the Isthmus. When referring to the tropics in this discussion we mean such conditions of climate and rainfall as occur in the Canal Zone.

ANOPHELES.

Of the many species occurring on the Isthmus the ones most commonly found are the white-footed species which include *Anopheles albamanus, Anopheles argyratarsus* and *Anopheles tarsimaculatus.*

Roughly speaking, where anopheles are numerous in houses at a settlement here, about nine-tenths or more of the specimens collected have been the above. The albamanus adults predominate, and roughly make up about half of the adults captured in dwellings. *Anopheles malefactor* and *Anopheles pseudopunctipennis* often occur also. It is most probable that all the five species mentioned are malaria carriers. They are always present when malaria increases, and when the adults disappear there is a corresponding drop in the malarial sick rate. This has happened time and again on the Isthmus during the three years 1906, 1907 and 1908.

OCCURRENCE AND HABITS.

While adult anopheles may be found in houses on the Isthmus at any time of day, as a general rule the best time to see them at rest and to take specimens is between sunrise and 9 o'clock.

Of course anopheles are more apt to be found in sleeping-rooms than in other parts of a dwelling, and as a rule are not present in uninhabited houses. Adults of species other than albamanus, argyratarsus and tarsimaculatus may be obtained more readily by obtaining anopheles larvæ and developing them in the laboratory than by searching for the adults.

The albamanus generally leaves the dwelling during the daytime. It is present and bites more readily after dark. However, it will bite voluntarily at any hour of the daytime, but does so mostly indoors or out of the direct rays of the sun. We have not yet any cases on record showing that anopheles will bite a person exposed to the direct rays of the sun. If anopheles are resting in vegetation near houses and such vegetation is disturbed, burned or removed, they will often seek shelter in the nearest buildings. This habit is common to other mosquitoes in the tropics. In a badly infested vicinity such a removal of the natural resting-place will send scores of mosquitoes into the nearby houses. It is not yet known whether the malaria-conveying anopheles, when numerous in a shaded area containing tall grass, brush and trees, will bite malarial persons resting in such places in the daytime, and remain in the vicinity long enough to transmit malaria to other persons that may come to rest, or sleep, in the same place in the daytime during the following weeks. It would seem as though this does take place, and, if so, it may have an important bearing on the status of malaria in the Canal Zone.

On the Isthmus some anopheles breed throughout the entire year. Of course, during the rainy season, which lasts from April or May to December, the anopheles are more numerous, as there are at that time more suitable breeding-places than from January to April inclusive (which period is known as the dry season). During this latter period a large amount of anopheles propagation goes on in streams and at the edges of the banks of rivers whose waters move too rapidly during the rainy season to be very favorable to the development of mosquito life.

At the island of Taboga, located in the Pacific and about nine miles from the city of Panama, very little, if any, malaria is present. There is not much communication between the city of Panama and this island except by the natives of Taboga, who come to the city to sell their fruit and generally return the same day or sleep in their small boats off shore. Most of the patients at the Taboga Sanitarium have been treated with quinin before arrival at Taboga, and are taking regular doses while at Taboga. In other words, there are some people at Taboga carrying the malarial germ in their blood, but not many. So far no anopheles have been noticed near the sanitarium. Toward the end of the dry season no anopheles larvæ can be found on this island, although they are present in the wet season, and it would seem as though the breeding season was more limited than is the case on the mainland. In other words, it would appear probable that the anopheles there have adapted themselves to the local conditions; that, for certain periods, the breeding stops until conditions for propagation are more favorable. Now it should be stated that Taboga Island is about three and one-half miles long by one and a half wide, has about one-half the rainfall of the mainland Pacific slope, and the air is much dryer. It is very hilly and has two streams that run down the hillsides throughout the year and other breeding-places in wet season. Naturally, in the Zone, during the dry season, as the shallow swamps dry up and the seepage water stops trickling from the hillsides, the anopheles change their breeding-places to the hillside streams which during that period contain many pools. They continue to multiply in such streams, which are identical in character with the streams at Taboga. The streams at both locations become less rapid as the dry season advances. In the mainland streams the number of breeding-pools or breeding-areas increases as the water gets warm and sluggish, and at Taboga, although anopheles are present on the island, we do not find larvæ in the streams in the dry season.

It should also be stated that we have recently taken anopheles larvæ from brackish water that contained up to 90 per cent. of salt water (sea water). These were obtained in the month of April, 1908, at Miraflores, a point about six miles or more inland from the Pacific. The tide level on the Pacific side at Panama varies eighteen feet or more. These anopheles were taken at the mouth of a stagnant river, into which the tide water entered at a time when it had practically no current. There had been no rain, and all evidence points to the

---

[*] Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-ninth Annual Session, held at Chicago, June, 1908.

fact that the eggs were depositd near or where the anopheles larvæ were obtained. Once, during 1905, it was reported that anopheles larvæ and pupæ had occurred in decidedly brackish water at Colon, within a mile of the Atlantic seashore. This was reported in the rainy season and a check examination of the breeding-place gave negative results. A very heavy rain had washed out the place where the anopheles were reported to have existed. Just what bearing this matter of possible development of anopheles larvæ in brackish waters containing upward of 50 per cent. of salt water would have on the malarial situation here is difficult to state, but it is well worth investigation. It may occur regularly at certain seasons only.

BREEDING-PLACES.

I have never had the opportunity to study and investigate methods of mosquito destruction in northern climates, and in forming an opinion of such work I have had to rely on a few written reports that I have been fortunate enough to obtain. On the whole, it would seem that the eradication of anopheles-breeding areas in the temperate zone and northern latitude is a much more simple matter than similar work in the tropics.

In the north the following conditions favor extermination:

1. The breeding season is short.
2. There is a period of drought in the middle of that season.
3. Growth of aquatic vegetation, algæ and grass is relatively slower.
4. Frequent cleaning of open ditches is not so necessary as in southern climates.
5. The rainfall is not heavy—relatively long periods occur between rains, hence the number of breeding-areas is relatively small.
6. The breeding-places are more accessible and easier to locate.

In the tropical and semi-tropical countries the destruction of mosquitoes is more difficult for the following reasons:

1. The ovidepositing continues each month throughout the year. The adults, generally speaking, are more numerous in the wet season (the wet season is May to December inclusive), because there are more breeding-places, which are favorable to complete development. In the wet season the breeding-areas seldom dry up. On most flat areas the soil becomes water-logged, vegetation grows rapidly and prevents evaporation of pools and also hides depressions in the land that contain anopheles larvæ. Then, too, a cow or horse grazing on such land leaves hoof-marks from two to six inches deep, which retain water in which anopheles larvæ may be found. Flat lands and low lands are thus troublesome for about eight months of the year.

2. During the rainy season the periods between rains are short. In comparing the antimalarial work in the north with that of the tropics, let it be assumed that our dry season corresponds with the summer season of drought of the United States. In the dry season here, which lasts about four months, and toward March and April, the small streams dry up and the larger streams and small rivers become sluggish. At this season the anopheles suit themselves to local conditions, and these large streams and small rivers which have become more or less stagnant become simply alive with anopheles larvæ. We thus have a large crop of female anopheles on hand at the beginning of the wet season. The original settlements and camps near which the Isthmian Canal Commission camps have been located were nearly all located near streams so as to have a convenient water supply. The country along the line of the canal is supplied with many streams which drain into the Rio Grande, Pedro Miguel, Comacho, Bas Obispo and Chagres rivers. These rivers pass close to the settlements along the line of the canal, and such settlements which are not far distant from one another, extend from Gorgona to Miraflores, a distance of about fourteen miles. Also it should be stated that water seeps from the sides of the canal excavation, and this makes a continuous collection of water in the bottom of the canal. Throughout the dry season, therefore, we have any amount of favorable breeding-ground in the canal bottom for a distance of from ten to fourteen miles at the present time, and the possible breeding area will increase as the construction of the canal progresses. In other words, and briefly stated, this means that anopheles propagation continues without much interruption throughout the dry season in the Canal Zone, in an area where about 70 per cent. of our employes and their families live. In fact this propagation of anopheles in the dry season is a very serious matter, and during past years the malarial sick rate at the settlements at Las Cascadas, Bas Obispo and Gorgona, where about one-third of our employés and their families then resided, was much higher in the dry season than in the wet season.

3. I have read of many instances in which apparently satisfactory mosquito destruction work has been accomplished in the United States by means of open drainage ditches, and, moreover, that such ditches gave satisfaction if cleaned out in the early spring, and once or twice during the summer. It is assumed that this means that such open drainage ditches need attention from two to four times a year only, during the six months, April to September. On the Isthmus and probably throughout the tropics, under average conditions, we could not consider such a mode of procedure, as it would give most unsatisfactory results. Such a ditch would become a veritable Mecca for anopheles. Assuming that the first rains of the wet season begin on May 1, then by May 15 we shall have probably from three to ten inches of grass in many ditches that were free from vegetation on May 1. The vegetation will retard the flow of water appreciably and anopheles propagation will soon follow. It should also be noted that the direct sun-rays enter the ditches having a general east-and-west course, and the bottom of all ditches are more exposed to the sun's rays, and for longer periods daily, than would be the case in northern latitudes. It must be remembered that raising the temperature of the water favors the rapid appearance and growth of algæ. As a general rule, a body of water containing green algæ affords breeding-places for anopheles. When such algæ are found in a stream, pond or ditch the larvæ of anopheles are generally to be found also. Apparently, the small fish and other natural enemies of the larvæ can not penetrate the algæ. We often find pools, ditches and edges of streams well stocked with fish which will readily take larvæ thrown to them or larvæ frightened away by removal of the algæ. But when sufficient algæ are present the mosquito larvæ thrive and live protected by the algæ growth and apparently the fish can not get at them. At all events large numbers of small fish that prey on larvæ and anopheles larvæ live in the same pool, ditch or stream, and the fish have no apparent effect upon the number of anopheles larvæ as long as the algæ are present. If the algæ are removed a new

full growth of algæ will often replace it within less than a week. These algæ are most troublesome. If a bunch of the growth is detached from the bank and pushed out into the stream the anopheles go with it, and finally it comes to a resting place. There may be many fish in the water through which the algæ float, but they do not succeed in getting many of the larvæ. The female anopheles seems to know that her young need protection, and she is evidently careful about the selection of the place where the eggs are to be deposited. The eggs are rarely, if ever, deposited in a fresh pool of water, or in water, unless algæ, grass, small stone or some other protection for the young larvæ is present.

4. In order to keep a ditch of low grade or a stream perfectly free from vegetable growth and algæ, so that the fish may have access to all parts of it, it would be necessary carefully and properly to clean out such a ditch or stream about every ten days. As we have had many miles of streams and ditches near settlements, the process would be excessively expensive. Our available labor is not intelligent, and consequently the cost of supervision is expensive or the work is badly done. With several rains a week, and with periods of two weeks at a time when we have showers almost every day, the rate of growth of vegetation in open ditches is exceedingly rapid. Such conditions probably occur only in tropical and subtropical countries.

5. On the Isthmus the rainfall is heavy. The periods between successive rainy days are short and during the rainy season the suitable breeding-places for anopheles are very numerous. The average rainfall on the Atlantic slope is 180 inches per year. The average rainfall on the Pacific slope is 80 inches per year. With excessively heavy rainfalls during a more or less continuous rainy period, the ground on the lowlands becomes more or less saturated with water, and small depressions in the ground become water-containers. The water is replenished before evaporation is completed, so that each such depression often remains a mosquito-breeder. The grass grows rapidly and helps to prevent evaporation, and also makes the location of all breeding-places difficult to find. You may readily imagine the difficulty of using ignorant labor on this class of work. On the Isthmus our laborers are not of a high order of intelligence, to say the least, and can not be left at work without supervision. As a rule, they take very little interest in sanitary matters, and but few are interested in the tasks they are directed to accomplish. The rain-water that falls on the hills is sufficient at times to cause seepage to occur on the flatter slopes toward the base, as well as on the benches on the hills. Often the rate of seepage exceeds the rate of evaporation for several weeks or more, and anopheles larvæ and pupæ are found on the hillsides and in places where such seepage occurs. The place or exact locality where the seepage crops out depends on the rate of rainfall and on its continuance. As both of these are variable quantities, the location of the places where anopheles larvæ occur will change from month to month. The inspection of and search for possible breeding-places must be extremely thorough before successful extermination can be accomplished. In 1907 we found anopheles larvæ occurring in seepage water on hillsides which had produced practically no seepage during the corresponding seasons of the three previous years. During very wet periods it is never known where the breeding-places will crop up next, and, consequently, we must be on the *qui vive* continuously. A small depression, even if only half an inch deep, provided it is kept supplied with water by seepage from the land above it, is sufficient for the propagation of anopheles.

6. While, in northern latitudes, the rainfall during the short mosquito-breeding season is relatively light, in the tropics the rainfall near the seacoast is heavier and more continuous. As a result, we must either keep the grass and brush, or jungle, cut short in order to locate the breeding-spots and assist evaporation, or else run the chance of passing by important breeding-areas which would mean unsuccessful results. In certain fertile lands vegetation will grow to a height of twenty to thirty inches or more per month in rainy periods.

METHODS OF MOSQUITO DESTRUCTION.

The methods used in the Canal Zone are the following: Fumigation, use of crude petroleum, use of larvacides, use of open ditches, blind drains, filling, tiling, and clearing of jungle.

Fumigation.—When the local breeding-places have been destroyed, and the necessary clearing of vegetation or jungle accomplished, if the anopheles persist in large numbers in houses or sleeping-quarters, they are killed by fumigation. We fumigate all sleeping-cars of construction trains leaving a malarial district. Before this was done it was not an uncommon thing to find large numbers of gorged anopheles in sleeping-cars of construction trains on arrival in a new district.

Crude Petroleum.—There are the same objections to the use of crude petroleum here as occur in the north, and also additional ones. The dense vegetation that occurs at the edges of ponds, ditches, etc., does not allow the oil to get at the places where the larvæ are present. The heavy rains wash the oil away—sometimes all of it. The oil unites with the algæ and forms a mat which sinks and at times leaves the surface free of oil. Even where oil is present on the water, or where sufficient is found to form a thin film in the cup used to dip out samples of water, well developed larvæ have been found living in such water several days after the oil was supplied. By mixing a little crude carbolic acid with the crude oil much more satisfactory results are obtained; but care must be taken, as there is a possibility of such water being used by natives.

Larvacides.—Phinotas oil is a preparation which is a most effective larvacide for us in the tropics. In doing work on a large scale and having to use native or other unintelligent labor, the cost of transportation of crude pertoleum is very high. In fact, at times it costs here from one to two times more than the oil itself, depending on difficulty of transportation. In using phinotas oil, of which a little goes a long way, this transportation charge is cut out, and a laborer can carry with him enough to last him for about three or four hours' work. under such conditions of distribution of breeding-places as occur here. In the Zone we obtained fair results with the use of crude oil, good results with use of oil and carbolic acid mixture, but we had to be very careful in using the latter, and generally to use it just before a heavy rain, and to see that nobody used the water in which it was placed. With phinotas oil we get very good results, especially in still water. Our anopheles larvæ occur here in large numbers in streams having varying rates of velocity. The volume of water in the stream changes, the banks are rough, sometimes practically flat, and at places almost vertical. The location of the bed of the stream or small river changes. Some of the streams have rocky sides and rocky or stony beds. In most streams fish are very plentiful and they eat some of the mosquito larvæ. In many cases we have cleaned the banks of rivers of vegetation and all algæ; small larvæ-eating fish have been present in large numbers, but many of the anopheles larvæ take care of themselves and live in spite of the fish being present. They hide under small stones and in the mud. The fish miss so many of them that we can not rely on fish here, if we expect to reduce the larvæ to a minimum. The smallest of these same fish (one inch long and larger), if placed in a jar of water containing larvæ, will take thirty or more in twenty-four hours, and yet in the streams they can not accomplish the results that we are expected to, and are achieving. Laboratory and field experiments with phinotas oil and other larvacides give completely different results, and the local conditions of climate, growth of vegetation and algæ, temperature, rainfall, topography, natural drainage systems, and quality of water and soil, have to be given proper consideration. We are obtaining good results in using phinotas oil in running streams by making weekly applications of phinotas. On the fifth or sixth day after application very young anopheles larvæ are again quite numerous, but careful examination fails to show the presence of well-developed larvæ when the application is properly made. Of course, all depends on the interest that the inspector takes in this work, and it is impossible to give too much interest to this matter. Unfortunately, we kill the fish by this operation, but then on the other hand, as the fish can not perform the desired results which we are otherwise accomplishing, they have to go.

Open Ditches.—Surface ditches are good here when shallow, provided conditions of grade, character of soil, etc., are such that said ditches will become dry very soon after the rain has stopped, and provided the heavy rains will not form deep depressions therein. It is not uncommon here to find new holes several feet deep in ditches that have withstood the effect of previous rainy seasons. If the character of soil is such that water will constantly remain in a low-grade ditch for two weeks or more, such a ditch is often an expensive and dangerous one. The fewer ditches of this character the better. In fact, on gently sloping or nearly flat ground, any system of parallel branch ditches leading into a main ditch would be a good system for Panama, if the object was to try to breed a maximum of anopheles in a minimum of time. Under the general conditions of soil, rainfall and temperature that exist here, it is most advisable to get along with as few open ditches as possible. In fact, ideal conditions would be to have none at all, except stone-lined ditches with mortar finish at the bottom. Subdrainage by tiling is the most economical method. In the north it might be advisable to use narrow ditches, about six inches wide, and about twelve to twenty-four inches deep, properly cut to grade. Here, in the dry season, large cracks, often two inches wide, occur in the ground, and the sides of ditches collapse. So a ditch of this character will block itself up, and ultimately the banks will take their natural slope. Again, in open ditches, we have the everlasting question of tropical growth, making it necessary to clean out the grass about every two weeks. We must clean out the vegetation, or use very large quantities of oil or other larvacide. The process is too expensive.

Blind Drains.—A blind drain is practically a miniature culvert covered with field stones. Before we were able to construct tile drains we used blind drains where plenty of field stones and loose rock was available. Such drains gave fairly good results. Early in our mosquito campaign we found that it was essential to remove the jungle near settlements, and to remove loose field stones. We dug ditches, laid flat stone on the bottom of these, then placed a stone at each side and a cover-stone on top. Above this was piled other stone. Smaller stones were again placed above this. Some ditches thus made gave satisfactory results for a period of three years, with no cost for maintenance. Several clogged up on one or more occasions and had to be made over again in spots. Where plenty of stone is available and must be removed from a field, this form of ditch is economical to make and, in the tropics, much more economical to maintain than an open ditch is, while anopheles larvæ do not occur therein. The boxes or openings in these blind drains that we used were about 6 by 10 inches, or of less area. The storm-water ran over the top, and within a few hours after the rain ceased all water was beyond access for mosquitoes. Although some of the blind drains were completely covered with vegetation and some soil, yet they performed their functions in a satisfactory manner. We opened up some of these drains when the flow of water in them became sluggish, but found no mosquito larvæ therein. The advantage of this type of drain is that there is no first cost for material, the field stones are disposed of, and there is no cost of maintenance except when the ditch clogs up. A good grade is essential for blind drains, and they will stand on a fairly heavy grade.

Filling in of Low Ground.—Whenever available, porous material, such as ashes or gravel, should be used, if the filling is to be made for mosquito destruction purposes only. It may happen that water seeps out on a hillside at different levels. If porous material is available, the mosquitoes can then be kept away from the water, which need only be kept a few inches underground. In filling low ground which is kept wet, or on which the water comes from higher ground, a ditch should be located and made sufficiently deep to cut off the subsurface water supply. Under certain conditions, if this is not done, we may fill in as much as two feet (with loose soil) above the original water-line, and yet water will ultimately ooze out through the new fill we make, even though there be a ditch through the middle of the newly made fill. It should be remembered, that, though the hillside surface is dry, there may be a constant flow a foot or more underground and we find here many instances where the low ground and ponds between hills are kept wet by this means.

Tile Drainage.—The use of tile drainage is the most economical and permanent method of destroying anopheles in the tropics. The work costs about 16 to 20 cents a foot and upward, according to the depth of trench, material to be excavated, and distance that the tile and covering stone has to be carried. Where there are no roads and transportation is difficult, or where rock is scarce, the cost per foot will run higher. The cost of tile in the United States is about as follows:

4-inch tile,	$ 30.00	per 1,000 feet.
6-inch tile,	55.00	per 1,000 feet.
8-inch tile,	90.00	per 1,000 feet.
10-inch tile,	135.00	per 1,000 feet.

In nearly all cases in the tropics, where the rainfall is heavy and vegetation is rank, it is more economical and satisfactory to tile-drain than to maintain open ditches, and the actual results in decrease of anopheles and of malarial fever where tiling is used speak for themselves. There is always an uncertainty about the results of drainage by surface ditches. A properly laid tile drain, as a rule, does not cost as much as an open ditch would cost to make, and to maintain absolutely free from anopheles larvæ for twelve months, in that part of the tropics where the rainfall is heavy. These tile drains, if given a flatter grade than 0.5 per cent., are apt to silt up. We have constructed some tile drains having as high a grade as 5 per cent. and covered them with plenty of stone to hold the tile in place. No failure has occurred in this grade. With light covering such tile would wash out. Where the grade of stream is very heavy it is often best to flatten the grade of the tile line and let it come to the surface at several points. The end of each one of a series of such lines of tile may end in a roughly made stone wall. The water can be made to discharge onto a stone floor at a lower level, and from there the water runs into the next line of tile. Tile-drainage systems here are not designed to take off all storm-waters. The bottom of the ditch is but slightly wider than the diameter of the tile, and is cut to true grade. The tile is laid in the bottom of the trench. If the bottom is soft it may be made satisfactory by ramming stone into it. If it is very soft and permanently wet, then wooden planks may be laid under the tile, but the tile must break joints with the planks. When the trench or ditch is completed the sections of tile are laid with the joints about touching, or with not more than about one-eighth of an inch clear space between successive joints. Also T's and Y's are located where necessary for branch tile lines. On very flat grades tile should not be used, and where open ditches of this character become a menace to health roughly-made stone ditches with mortar finish at the bottom give satisfaction if kept to grade. Above the tile in tiled ditches we place stone of all sizes, and on top of this stone filling we generally lay smaller stone to prevent earth from clogging up the small openings between adjacent tiles. The last stone covering, or stone nearest the surface of the ground, forms the bottom of the ditch, in which the storm water flows. The trench made to hold the tile is not filled up even with the original ground surface, but generally up to about one foot below the ground surface. At times of very heavy rain the tile may run full, the spaces between the cover-stone may be full of water, and in addition there may be more or less water running over the top of the cover-stone. Very soon after the rain stops all the water finds its way into the tile. As previously stated, care must be taken of the water seeping from the hillsides, and in order to cut off this water it is necessary to run one or more tile ditches to grade and more or less parallel with the contour of the seepage outcrop. In many instances this tapping of water sources makes the ground in low spaces become dry and drainage or filling of them becomes unnecessary, as the surface of the low ground is then higher than the water line in the tile. In hollows, between hills that carry large amounts of seepage water, even if the space between the hills is only ten or fifteen feet wide, it often happens that a ditch in the center of such a hollow will fail to drain it completely. Tile lines following the side of the hill will do the necessary work, provided the planes of seepage are pierced by the tile trench. At times, in order to get the required grade, it may be necessary to carry some tile lines as deep as nine feet under ground for short distances. Work of this character rapidly increases the cost of tile ditching work. Tile drainage can not be done at random. The whole drainage scheme for any one district should be properly planned, levels taken, grades established, and an approximate estimate of the cost of the work considered before any work at all is undertaken. The ground must also be gone over in the wet season in order that the conditions that will naturally exist at that period may be appreciated.

Clearing of Vegetation.—All authorities agree that during time of heavy wind mosquitoes seek shelter. As a rule they then rest in tall grass or brush. It would appear as though this matter of shelter or of resting places is of much greater importance than is generally supposed. There is no doubt but that it is of vast importance in antimalarial work in the tropics. If we have a settlement surrounded by tall grass or heavy brush, even though we destroy all near-by breeding-places, the adult anopheles often remain present for quite some time. If we remove all vegetation within 200 yards or more of the houses, as a rule, we have the following results: Directly after the clearing it is common to have an unusually large number of anopheles and other mosquitoes come to the houses. These gradually disappear, and then afterward they become far less numerous than they were before the clearing was made, provided the grass is kept short and provided no near-by breeding-places are neglected. But along the edge of the clearing so made mosquitoes will continue to be present for quite a long time. Aside from this question of getting rid of adults, the clearing of jungle is essential in order to locate all small breeding-spots which may occur in different localities from time to time. It also prevents water-containers being hidden in the grass, such as tin cans, etc., and hence prevents the occurrence of stegomyia. With heavy jungle near houses, or even with tall grass present, we are never sure that all small breeding-places have been located. There occur short periods during which the ground may become wet and very soft. Such local conditions may last for a period of three weeks only during an entire year. It is the small breeding-places that are apt to be overlooked. The sanitary service of the Canal Zone extends over a territory forty-two miles long, with houses, camps and settlements scattered along the entire length and there are many places that have to be watched.

RESULTS OF THE ANTIMALARIAL WORK ON THE ISTHMUS.

Several years ago the outlook was not very encouraging. The malarial sick rate at certain camps ran high and many cases of malignant malaria occurred. In fact, at some settlements, in addition to the light cases among the laborers, which were kept for two or three days in the local "sick camps," we also sent to the hospitals as many as 10 per cent. of the working force during weekly periods. These cases were of more severe types of malaria than those kept at the sick camps. Such a sick rate as this interfered largely with the work of canal construction. At one settlement in the Gorgona district where this occurred the malaria has since been very largely reduced, and in April, 1908, out of over 1,100 employés, during a period of twenty-eight days, but ten hospital cases of malaria occurred. The ratio of reduction, if weekly periods were considered, would be about as 110 is to 2.5. Of course this is an exceptional case, but also it indicates what it is possible to accomplish under adverse conditions.

In carrying on an antimalarial campaign there are times when results look very discouraging, but success is generally possible. There was one case in which all breeding places were under control, and several careful and most thorough searches failed to locate a single anopheles breeding-place within a quarter of a mile of the infested camp where adults occurred. They remained for about three months and then disappeared. Strangely enough, the disappearance of anopheles and the marked decline in malaria occurred at the beginning of the rainy season. This is the time of year when we always get an increase of adult anopheles at our camps. It is difficult to give an exact reason for what occurred. I am inclined to think that the anopheles had previously come from near-by breeding-places and remained in the vicinity, although apparently no near-by breeding-places remained. More recently we had a somewhat similar state of affairs at San Pablo, except for the fact that the anopheles present in the daytime in this case were fewer and the malarial sick rate lower. The fact is that the anopheles remained and the malarial cases persisted, apparently in spite of the absence of local breeding-places. In each of the two cases cited the malarial sick rate dropped soon after the disappearance of the adult anopheles from the vicinity of the camps in daytime. At the present time the type of malaria occurring in the Zone is much less severe than in former years, and, moreover, the cases of malignant malaria are relatively small in number.

We have installed considerable tile drainage during the past year and the results of such work are exceedingly satisfactory. The malarial situation in 1907 was a vast improvement over that of 1906. So far this year, aside from light cases at the local sick camps, the percentage of employés sent to the hospitals with malaria averages about 75 per cent. less than during January to April, inclusive, of last year. This is for the territory between La Boca, on the Pacific side, and Gatun, where the locks are to be built. This territory is forty-two miles long and Gatun is about six miles from the Caribbean Sea. At the end of April, 1908, we had the lowest weekly sick rate yet reached. During the week ending May 2 only one malarial patient was sent to the hospital for each 1,000 employés at work.

A very good illustration of the results that may be achieved, under very trying circumstances, by the combined effects of tile drainage, clearing and use of larvacides is the work now being accomplished at Porto Bello. A laborers' camp was started at Porto Bello (which is located about twenty miles from Colon) on about the first of the year. Mr. Henry Simms, our sanitary engineer, who planned and installed a large part of the tile drainage work in the Zone, took charge early in March. At that time about 15 per cent. of the force were in the hospital with malaria each week. For the week ending April 28 the malaria hospital sick rate had been reduced to 6 per cent. We have every reason to believe that within less than a year Porto Bello will be as free from malaria as any settlement in the Canal Zone.

Isthmian Canal Commission, Department of Sanitation.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. LE PRINCE AND WHITE.

Dr. Walter Wyman, Washington: I attended the International Sanitary Convention of the American Republics in Mexico last December, and I was surprised to hear the president of the Superior Board of Health of Mexico declare that they believed that they had eliminated yellow fever from their republic. He emphasized the statemnt by declaring that the forces which had been used in the elimination of yellow fever—clerical force, officers in the field, and equipment—were now being devoted to the elimination of malaria. It struck me that this signalized a stage of very great progress in the elimination of epidemic diseases. The Mexicans are earnest and scientific in their work, and I have no doubt will eventually be as successful with malaria as they have been with yellow fever, and what has heretofore seemed to be almost impossible will, in the course of a few years, have been proved possible. As you all are aware, a victory over malaria will be quite as great a victory as that over yellow fever. Dr. White's paper brings out very distinctly the point that we must get rid of yellow fever forever by eliminating it from all the ports where it prevails in the western continent. It is peculiarly a disease of the western continent, and I am happy to say that the International Sanitary Conventions, which are held every two years by the American Republics, are having a marked influence in the Central and South American republics. The people there realize that the conditions which perpetuate this horrible disease of yellow fever must be done away with; that any sanitary work done to eliminate yellow fever will also tend to remove the cause of many other diseases; and that if they can eliminate one disease they can eliminate the others. The next convention will be held in Costa Rica in 1909. In Rio de Janeiro they have made great progress in sanitary matters, and it seems to me that the influence of the sanitary conventions is more needed and will be productive of more good in the smaller republics with their numerous small ports than in the larger republics with large ports, such as Rio de Janeiro. When the governments of these smaller republics, like Salvador, Guatemala, Honduras, and Costa Rica and Ecuador are induced to sanitate their ports and do away with conditions which breed mosquitoes and develop yellow fever, we shall then not be alarmed when the railroad trains come through from these places and make quick connection with the United States. I think that the outlook is very encouraging, and that within a quarter of a century a great deal of this trouble that we are discussing now will be a matter of history.

Dr. Seneca Egbert, Philadelphia: The mosquito does not bother us in the north very much, though we are glad to know how to get rid of the pests, as they disturb our summer vacations. But the public should be educated to the fact that we can fight disease by material means and that disease is a product of material factors; that typhoid, tuberculosis and other diseases come from germs; that the mosquito bears the disease germ, and that if we put him out of business he will cease bearing the germs, and that we do not need Eddyism. General knowledge of victories such as we have had in New Orleans will wipe fallacies like Eddyism out of existence. After a while people will learn that they can not afford to believe in Eddyism or any theory that does not take into consideration actual factors of disease. I accordingly believe that one of the most important influences that organizations of this character serve is the education of the public.

Dr. John Pitt Matthews, Carlinville, Ill.: One of our American boys went down to the Canal Zone and contracted yellow fever, but survived the attack. Colonel Gorgas appointed him one of his inspectors. When he came home on a furlough he taught the whole town and that part of the country that malaria was due to the mosquito. He had placards and pictures of the mosquito in the different stages of development of the larva and the mosquito itself. I demonstrated some of these pictures at the county medical society, and showed that our Egypt down there was infected with the same malaria and the same mosquito that was causing trouble in the Canal Zone. My father, who has been in the practice of medicine for forty years, says that forty years ago the curse of the country was the malarial infection from the farms that had just been plowed and brought under cultivation. Everybody shook all the time from malaria. The draining and improvement of the farms has eradicated malaria from our section.

Dr. George B. Lake, Wolcottville, Ind.: The public in general does not yet realize that they need the information that we are ready to impart; and for the next few years, until they begin to realize that we have something important to give, we must compel them to listen. Then they will come to us.

Dr. O. C. Breitenbach, Escanaba, Mich.: The grand achievements of prophylactic medicine in the prevention of yellow fever and malaria and kindred tropical diseases, largely through the Public Health and Marine-Hospital Service, have been made possible only by the fact that this work has not been subjected to political despotism. Education is important and necessary in the eradication of preventable diseases; and yet it seems to me that the greatest stumbling block in American cities and smaller municipalities is the political ring. The local health officer, a great factor in the field of prophylactic medicine, is often prevented by political influence from doing his duty. Not until public health work shall be divorced from politics will efficiency in this department inspire respect and praise. There is, however, ground for hope. Grand Rapids, Mich., and many other larger cities, by making the health commissioner irremovable as long as he does his duty, have inaugurated a movement that I trust will be an incentive to other communities. Mayor Busse, of Chicago, submitted the vacancy in the office of health commissioner in Chicago, which was not under the control of a civil service board, to the Chicago Medical Society and a committee of prominent business men, to be filled by the candidate nominated by them. He accepted their nominee, Dr. Evans, although differing with the latter in politics. Chicago to-day is proud of the work that Dr. Evans is doing, and his sanitary crusade is notable. We all strongly feel the necessity of divorcing public health work from politics. Until this reform is accomplished all sanitary progress will be hampered.

Dr. E. L. Munson, Fort Sheridan, Ill.: It seems to me that Dr. Wyman's point with regard to the necessity of cleaning up yellow fever plague spots could be strengthened by adding a time limit. This time limit could not safely be extended beyond the time of the completion of the Panama Canal. The necessity for keeping yellow fever out of the orient, I think, was brought out several years ago, and its importance has probably struck every one who has had to do with sanitary work there. The handling of yellow fever in this hemisphere is unquestionably a tremendous task, but at least it is possible; but I believe that the control of yellow fever transported to the orient will prove a task almost impossible, because of superstition, caste feeling, racial dislike, and other factors. It is important not only to clean up all the yellow fever foci on this continent, but to clean them up as quickly as possible, and before the means of transportation have been improved and the time of communication shortened, else we shall have to fight it coming back to us from the Philippines, from southern China, and possibly a large part of the tropical orient. It should be a relatively easy matter to prevent it from getting in—an enormous task, but possible—and I think that we ought to use every means possible to induce the infected parts of South America and the West Indies and Central America to abolish the yellow fever infection from their borders by such time as direct communication with the tropical orient through the Panama Canal can be accomplished. The next eight or ten years constitute about the limit of time that we can afford to tolerate these active foci of yellow fever.

Dr. H. B. Hemenway, Evanston, Ill.: The only way to control any communicable disease is by authority, whether municipal, state or national. The first point in the study of any of these diseases is the collection of accurate data, which are hard to get. The representative of this Section in the delegate body should urge that the Association at this time pass resolutions in favor of a national department of health. A great political gathering will be held here in a few days, and it would seem that when the delegates come and see the evidences of the strength of the medical profession it ought to impress them as never before, and they ought to be willing at least to introduce a plank in their platform relative to a department of health. The work which Dr. Evans, for example, has been doing here in Chicago, is an illustration of what one man, the right man, can do. A man who is willing to devote his whole time to that kind of work is worth a great deal more than any community is willing to pay him. A United States senator from a sister state wrote recently that his attention had been so much occupied in studying law and politics that he had not had time to consider anything relating to the public health. Again, in the city in which I live, the attorneys of the city are paid $3,300, while the Commissioner of Health is paid but $600, and he is the only medical man connected with the city government. Within a year we have had demonstrated the absolute necessity, not only for the examination of milk itself, but the examination of the origin of that milk. That is expensive, yet the city council has managed to cut down the appropriation for the milk examination to $150.

Dr. Laura A. C. Hughes, Boston: The only way to educate the public is in the matter of prophylaxis. Authority is helpless. We have laws for all criminals, and yet we have a great deal of criminality. In Boston we are endeavoring to do something in that line by giving in the high schools some instruction in preventive medicine. We give minor instruction in bacteriology, teaching the classification of the bacteria, and some of the diseases that are likely to result from the different bacteria. The teachers take up this matter readily, and become much interested, as, for instance, in the *Bacillus tuberculosis*. In teaching about the rod and spiral coccus and some of the diseases which arise from the different germs we find the common people much interested and much more careful not to spread the disease. They are more willing to cover their milk and cream. We have not the yellow fever and malaria so much to contend with, but we have the mission of educating the people in simple matters of bacteriology. This, to my mind, is helpful in preventive medicine. It is just as applicable in the north for tuberculosis and scarlet fever, etc., as it is in the south, and I think if the profession generally were interested in giving this kind of instruction in the public schools there would be little opposition to it. As Dr. Burrell told us this morning, Harvard Medical School could not contain those who went to hear instruction in preventive medicine and medicine in general. Those were public lectures given in a way that all could understand. We are each in our own locality able to start a little focus of enthusiasm and instruction. I have been trying to do my share in Boston in the public schools and even the high schools the last four years by giving this instruction in bacteriology and in simple methods for the prevention of preventable diseases. I recommend it to every one of you as being entirely feasible.

Dr. John M. Beffel, Milwaukee, Wis.: Whether a national health department shall be under the head of a special secretary who shall occupy the position of cabinet officer or be under another cabinet officer is immaterial. The necessity exists for the establishment of such a department in order that real, thorough educational work may be carried on by the various states. To-day there is in regard to communicable diseases of all kinds a woeful lack of accurate information—that is to say, material that is accessible to physicians, and that can be readily used in educating the people. If we attempt to combat tuberculosis we are immediately confronted with a hundred and one different problems—the question of exercise, the sanitary condition of shops and places in which men work, the hours of labor, the wages paid, and child labor. In order to do any accurate work whatever it is necessary to have accurate information along each one of these particular lines; so it is necessary that we have some central organization which would collect from the various states this information, to be used by states or by municipalities in other parts of the country. When we look around at the water supply in the rivers and lakes, and realize that our great lakes are lined with cities that are pouring their sewage into them, that the Hudson River is a cloaca of infection from Albany to the sea, and that the Ohio River for a thousand miles is a cesspool which, when its banks overflow, carries back to the lowlands organic material containing germs of infectious disease and breeding various disease-bearing insects, it seems to me that here is a problem for original research work—a line of work which can not be taken up by the municipality or state, but is properly the function of the central government. If it is the function of the government to investigate yellow fever in Cuba and the Philippines, certainly it is the function of the government to investigate any of the preventable diseases in the United States. The death rate in the United States of 650,000 a year from preventable diseases stares us in the face—during the last four years 2,600,000 preventable deaths and a possible death rate of ten million of the eighty million of our present population from tuberculosis. It seems to me that it is as much the duty of the government to do something whereby those ten million souls can be saved to usefulness in the world as it is to look after the health of our island possessions.

Dr. W. A. Evans, Chicago: I believe it is well established that we have no stegomyiæ in Chicago, and that in this part of the country the stegomyia is not found north of the vicinity of Cairo. During the yellow fever epidemic years, yellow fever patients have been allowed to come to Chicago without any particular control. In 1898 a patient came from Natchez or Vicksburg, and died in this city. There was no spreading from it, and no particular effort was made to prevent spreading. We have anopheles in great abundance, but probably our mosquitoes have not been infected with malaria for a great many years, though in the early history this part of the country was probably as malarial as any part of the country. Before the drainage ditch was dug we not only had malaria but many other semitropical diseases. At Cook County Hospital we had cases of tropical dysentery almost all the time. The explanation was given that they were due to the upturning of the earth, but probably the explanation was that the negroes brought up from the south to dig the canal came up with a subinfection, and this was responsible for the moderate spreading of the disease through our own people. Again, in 1898, when the soldiers came back from Cuba, they brought malaria, and it spread. In each case the destruction of the mosquito was a matter of a short time, and after a few years there was nothing of the sort left in the community. We have had a large number of mosquitoes. We do not believe that they act as hosts for disease here. They serve to call attention to the fact that even a community such as this can easily become infected. There is no reason why Chicago should not be as free from mosquitoes as some of the more southern points now are. For the education of the people, six or seven years ago, the Chicago Medical Society started public lectures. A public lecture is given in the Public Library building every Saturday night from early fall until late spring. We have branch societies all over town which are all interested in the organization in their part of the city, and some of them have lately been holding public lectures in the small park houses. The Department of Health has given a great many lectures this winter. I have averaged more than one a day all winter long, and some days have talked four times a day on health subjects. We talk to schools, clubs, churches, every business organization in town and to everybody that will listen. I have talked on health to audiences as large as three thousand and as small as nine people. Every large business club in Chicago has its committee on health. The Commercial Association, an effective and hustling business organization composed of several thousand of the best and most active business men in this country, occasionally has a well-attended meeting at which questions of health alone are discussed. The Commercial Club, our strongest organization, devoted an evening not long ago to the question of consumption. They have an active committee on health, the members of which are millionaires, which within the last six weeks has spent two afternoons in the Health Department. We get out two little bulletins. One appears every week in an edition of about 8,000 and is gratuitously distributed to every physician, every teacher and every preacher, and some others in the city of Chicago. Last week's issue was devoted especially to consumption and to its early diagnosis. The issue for this week shows especially the death rate from and the causes of diarrheal diseases, particularly typhoid fever. During the winter we talked on the subject of ventilation, pneumonia and consumption. Now we shall talk on food and water, especially milk and water. We send out articles to the paper on Sunday afternoon because the Monday morning papers need material and will give it more space than on any other day of the week. The papers treat us very kindly. They give these articles a great deal of space, and every metropolitan daily in the city has helped editorially, certainly on an average once every two weeks, and I think our most influential paper, the *Tribune*, has an editorial at least once every week on some live question. Then we get out a leaflet for another group, the foreign-speaking people. We found that we were not getting, as we should like to, at the Pole and the Bohemian and the Italian. This leaflet, on one subject at a time, goes to their publications, and is perhaps printed in foreign languages. We take up consumption, for instance, and show its extent and its effect on trade. One leaflet was on consumption among negroes, showing that the negro has about four times as much consumption as the white man. As soon as the negroes read this article they organized a tuberculosis society. Their meetings have been frequent and largely attended. Their organization has handled cases, and there is much evidence that they intend to handle the consumption problem of the negro for themselves. Those are the most important things that we are doing in the way of public education. I feel certain that the people are more alert on this question in the neighborhood than they are in most communities.

Dr. J. H. White, New Orleans: In reply to Dr. Hemenway and Dr. Beffel, I have lingered under the impression that we had a bureau of public health to which I had been devoting the twenty-five best years of my life. Under that bureau I have had the honor (and if I never do any other good work in my life I shall consider that I have done one) of extinguishing the yellow fever in the United States, the first time this was ever attempted through the destruction of the mosquito. There has been much work done under that bureau, and it simply remains for congress to increase the appropriation. Then all the information wanted will be furnished to the state and municipal authorities. The bureau is only too anxious to carry on this work if it can get the money. There are many state health officers who know this and who are in splendid accord with us. I know that we are a bureau of public health whether we ever become a department or not, and, furthermore, I know that when the United States needs men to do sanitary work, and we have not enough, we have only to go to the corps to which the President of this Section belongs, and we can get others. If we have not a public health service in the United States to-day then no nation has one. I am in hearty accord with Dr. Munson as to the limitation of the time when yellow fever shall be wiped out of the American continent. It will be a stupendous task, but if the other nations have not the men to do it we can loan them the men. We can wipe it out and it can be done in five years instead of ten. There are stegomyiæ in the Hawaiian Islands and in Guam, and as surely as we get the Philippines infected then so surely we will experience what was said about Cuba that it "has been a central hell, disseminating disease and death to all mankind." The Philippines will double discount Cuba if they ever become infected. It will be horrible beyond compare. I am delighted to hear what has been said about the education of the public in the city of Chicago. What Dr. Evans is doing is exactly what I had in mind. This is what we are trying to do under stress and strain in the city of New Orleans. All honor to Dr. Evans.

Dr. H. M. Bracken, St. Paul, Minn.: It is authority and funds for our present national bureau of public health that are chiefly needed. If we were pigs and cows we could get all the money required. Every one knows that there is a Bureau of Animal Industry, but very few seem to know that there is a U. S. Public Health and Marine-Hospital Service.

Dr. N. K. Foster, Sacramento, Cal.: I want to bear my testimony to the efficiency of our present national health department. I think that if we would pay less attention to enlarging our sphere of action by urging a special department in the cabinet, and insist that our representatives support the magnificent department that we have already, we should derive a great deal more good from our effort. When plague broke out last summer in San Francisco the Marine-Hospital Service took charge at the request of the state and city boards of health. The plague had a strong hold. The rats were infected all over the city. Cases came not largely from the Chinese and Japanese but from white people, and were scattered all around. In a few short months, by the efficient work of the Marine-Hospital Service, it was practically stamped out. We do not expect that it will be entirely stamped out for the next year or two, but since the first part of January we have not had a case. If the work is kept up and the Marine-Hospital Service is properly supported the plague will be stamped out from the Pacific coast. The departments are doing excellent work, and if we can unify them it seems to me we shall take a step in advance which will some time lead to what the most radical want.

DR. H. B. HEMENWAY, Evanston, Ill.: We have an excellent medical and surgical administration in the United States Army and Navy, and we have also a Public Health and Marine-Hospital Service. In this country there is not enough authority given to the medical man. We all know that the medical army officer has not the authority which he should have and which some countries, Japan, for instance, give to the medical officer. At the time of our war with Spain, after the surgeons made requisition after requisition for quinin the quinin was not forwarded until the need for it was past, and when finally a chaplain went up to a certain brigadier-general and asked if he could not use his influence to hasten on that quinin, the brigadier-general ordered the chaplain under arrest. The trouble was that there was no authority. I am second to no man in my admiration for the work which has been accomplished by the Public Health and Marine-Hospital Service, but this service, as it exists to-day, is coupled with the management of hospitals which have been in existence a long time for a specific and very limited use. The government has been using that old service, throwing on it a certain limited sanitary work. For efficiency the public health service should not be dependent on marine hospital management. Vital statistics ought to be under the control of the Bureau of Public Health, not the Bureau of Commerce and Labor.

CLINICAL AND MEDICOLEGAL SIGNIFICANCE OF SLIGHT TRAUMA TO JOINTS.

SIDNEY LANGE, M.D.
Radiographer to the Cincinnati Hospital.
CINCINNATI.

The Roentgen era has added much to our knowledge of joint pathology and has made possible a broader classification and a more comprehensive therapy of joint disease.

In the production of joint disease trauma undoubtedly plays a most important rôle. The trauma may result in a gross lesion of the joint, it may be the determining factor in the localization and growth in the joint structures of micro-organisms already present in the blood or lymph stream, or the trauma may initiate degenerative or chronic inflammatory changes in the synovial elements, changes which may in time impair or destroy the integrity of the joint. It is to this latter class of cases that attention is directed.

The histologic elements making up a joint are of comparatively low organization and scant vascularity. Degenerative and chronic inflammatory changes of a fibroid or calcareous nature are, therefore, very prone to occur in the joint tissues. Such changes are not infrequently initiated by some trauma to the joint, often so slight that it may have been overlooked by the patient.

Furthermore, the close relation of the bone-forming elements to the synovial sac makes new bone formation about the joint not an uncommon occurrence. Such new bone formation is usually the accompaniment of chronic inflammation in the joint, an inflammation which is so often excited by some slight trauma. A fall or strain may have ruptured a ligament, bruised or torn the periosteum or torn loose a small piece of cartilage or a splinter of bone. Chronic inflammation with fibrous tissue and new bone formation follows.

Such changes about a joint differ from similar changes in other parts of the body in that the joint changes are so often progressive. A fibrous or calcareous change in its incipiency may or may not interfere with the function of the joint, but the mere presence of such changes in or about the joint constitutes a hindrance to the free movements of the joint and an irritant, and the process which gave rise to this irritant becomes progressive. Thus what was originally a conservative effort on the part of Nature becomes, in the synovial regions, an irritant, and each new conservative effort gives rise to more irritation. A real vicious circle results. Too often this vicious circle accomplishes the permanent functional ruin of the joint. This is especially true in large joints, such as the knee, in which the movements are violent and the strain considerable.

These chronic joint changes are usually slow in developing; from one to ten years may elapse between their inception and the production of marked functional joint impairment. The causal trauma is thus often overlooked or forgotten.

The Roentgen picture of these joint changes is often of the greatest value and the only means of arriving at the true nature of the condition. The joint examined immediately after the slight injury may show nothing abnormal on the skiagram; or there may be evidence of some effusion into the joint or there may be seen a detached splinter of bone usually at the insertion of a ligament. Again, there may be a cracking off of the articular margin of the bone or a distinct gross fracture may be present. Such injuries are usually treated by rest and fixation of the joint for a few days to several weeks, and recovery may be apparently perfect. Indeed, in the slighter cases the patient may not seek medical attention at this time After a variable period of time, impairment of the strength and function of the joint may gradually develop, with or without pain. The Roentgen picture is now often characteristic. Minute or gross changes in the joint may be evident. There may be slight irregularities in the contours of the articular margins. Bony spicules may be seen here and there. Joint contours, instead of being smooth and nicely rounded, may be uneven and of grotestque shape. Bony spurs and outgrowths are seen in the more advanced cases. Loose bodies may be present in the synovial sac. Ossified masses (tendinitis ossificans) may be seen developing in the ligaments, especially near their attachment to the bone, or there may be a bony outgrowth into the ligament of its point of attachment. Bony masses may be seen in the surrounding muscles (myositis ossificans), which masses play an important part in interfering with joint movements. If the original injury has been a gross fracture there may be noted an excessive callus formation around the fracture with irregular outgrowths from the callus.

The changes being progressive, the ultimate picture may be not unlike that of arthritis deformans. True arthritis deformans may be ruled out, however, if the other joints of the body on examination are found normal.

Constitutional tendencies play an important part in the production of joint changes. Fibroid and calcareous changes about joints originating from trauma are much accelerated and aggravated by an accompanying constitutional state favoring their development. Given a patient of distinct gouty or "arthritic" (if the term be permissible) habit, the chances for chronic joint changes following trauma are much increased. This tendency is more or less marked in all arteriosclerotic individuals past 40 years of age.

The significance, then, of slight trauma to joints is its bearing on prognosis. The possibility of such joint changes following trauma must always be borne in mind and a guarded prognosis must be made in many joint injuries, especially those occurring in individuals past 40 years of age and of arteriosclerotic or gouty habit.

From a medicolegal standpoint these chronic joint changes are of much interest. Not infrequently claims for damages or accident insurance are made on the basis of joint changes, developing months or years after the original injury to the joint. Since such joint changes may undoubtedly be initiated by a slight traumatism to the joint, it would seem that such patients have just claim for damages, although in any given case it may be difficult to prove that the original trauma stood in direct causal relation to the subsequent joint trouble.

I have recently seen two such cases, one a hypertrophic arthritis of the wrist resulting supposedly from a fall on the hand two years previously, and the other an elbow which could not be completely extended because of a bony mass between the head of the radius and the articular surface of the humerus, resulting supposedly from a slight trauma some time previous. Both patients were in litigation to recover damages for the injury, but both lost in court.

There is another type of joint trouble which follows slight trauma, in which conditions are reversed. In this type of case the joint changes precede the trauma, but the symptoms are latent until called into being by the trauma.

It has been frequently observed that the changes of true arthritis deformans may be present in one or more joints without giving rise to any symptoms in these joints. The symptoms may, however, be lighted up at any time by some trauma to the joint. In the routine examinations at the Cincinnati Hospital this observation has been repeatedly verified. In the examination of joints of patients referred to the Roentgen laboratory for a supposedly acute traumatic synovitis due to falls many of these joints show all the changes of an advanced arthritis deformans, and yet such a patient will give no history of trouble with the joint previous to the injury. This observation has been made most frequently on the knee joint. An *x*-ray examination of the uninjured (supposedly normal) knee will show practically the same changes, although the joint functions perfect and painlessly. When the symptoms are once lighted up in these joints by the trauma they rarely disappear completely but run the characteristic course of arthritis deformans, namely, with remissions and exacerbations. The possibility of an underlying arthritis deformans should always be borne in mind when a traumatic joint inflammation refuses to subside under the usual treatment.

The following case illustrates the medicolegal phase of this circumstance:

Patient.—Mr. K. (referred for *x*-ray examination by Dr. Maloney), aged about 55, suffered a severe strain to his left knee in a railroad accident. The immediate symptoms were so slight that the patient continued on his feet and at his occupation of railroad conductor. In about ten days he took to his bed and was confined there several weeks, apparently because of delayed shock. When he got up again he complained of some weakness in the left knee and some pain. This pain and weakness was especially marked when the knee was fatigued and the symptoms became progressively worse during several months, after which I was asked to make an *x*-ray examination.

Examination.—At the time of examination the knee was slightly swollen and slightly tender over the internal aspect, but complete flexion and extension were not painful or restricted. The *x*-ray examination revealed no fracture or other gross injury to the joint, but the characteristic changes of arthritis deformans were present; bony irregularities, spicules, lipping of articular edges and loose bodies were seen. The uninjured (supposedly normal) knee was then skiagraphed and the same changes were noted.

Here then was a case of well-advanced arthritis deformans but symptomless up to the time of the trauma. The patient made a claim for accident insurance, which was allowed and undoubtedly justly. For, although the chronic joint changes preceded the injury, the injury lighted up the symptoms which now refused to subside. In the absence of such an injury it is reasonable to suppose that the patient would have continued to enjoy the full use of his knee for years perhaps. For the uninjured knee was evidence to this possibility. Hence the patient had a just claim for damages or insurance, although the pre-existence of the chronic joint changes should have modified somewhat the amount of the claim.

THE REGISTRATION OF VITAL STATISTICS.*

CRESSY L. WILBUR, M.D.
Chief Statistician, Bureau of the Census.
WASHINGTON, D. C.

I feel that I may reasonably take for granted the validity of the principle that complete and trustworthy vital statistics are the very foundation of sanitary work and absolutely indispensable in the daily duties of officers of the public health.

The means of obtaining such statistics were laid down in the "essential requirements" formulated some years ago by the American Public Health Association and the Bureau of the Census, and only last month reaffirmed, as "statistical rules," by the American Public Health Association. These principles have formed the basis of many successful laws, and no legislation in this country that has disregarded them has been successful. They are so important that it is worth while to repeat them:

ESSENTIAL REQUIREMENTS FOR REGISTRATION OF DEATHS.

1. Deaths must be recorded immediately after their occurrence.
2. Certificates of death of standard form should be used.
3. Burial or removal permits are essential to the enforcement of the law.
4. Efficient local registrars are necessary.
5. The responsibility for reporting deaths to the local registrar should be placed on the undertaker or other person having charge of the disposition of the body.
6. The central registration office should have full control of the local machinery, and its rules should have the effect of law.
7. The transmission and preservation of returns should be provided for.
8. Penalties should be provided and enforced.

ESSENTIAL REQUIREMENTS FOR REGISTRATION OF BIRTHS.

1. Births must be recorded immediately after their occurrence.
2. Certificates of birth of standard form should be required.
3. Some check is necessary to secure enforcement of the law.
4. Efficient local registrars are necessary.
5. The responsibility for reporting births to the local registrar should be placed upon the attending physician or midwife, and upon the parents if no physician or midwife was in attendance.

---

* Paper read before the Conference of State and Provincial Boards of Health of North America, Washington, Sept. 25, 1908.

6. The central registration office should have full control of the local machinery, and its rules should have the effect of law.
7. The transmission and preservation of returns should be provided for.
8. Penalties should be provided and enforced.

Those who have had to do with public health work are aware how inadequately deaths and the causes of deaths are still registered in the United States. Not quite one-half of the population of the country is yet included in the "registration area," which relates to deaths alone. Not a single state has yet qualified as having approximately complete (90 per cent.) registration of births.

It is, of course, well known that earnest efforts are being made to extend effective registration of vital statistics; that improved laws have been recently passed in many states; and that the great American Medical Association, the American Public Health Association, the Conference of Commissioners on Uniform State Laws, and the Bureau of the Census, have joined in the preparation of a model bill, which will be presented in several states next winter for legislative action through the aid of the state sanitary authorities. If the work already undertaken should meet all possible success, we might have nearly or quite two-thirds of the entire population of the United States in the registration area for the next census year, 1910.

But it may not be fully realized—and to this I desire to call the special attention of sanitary and registration officials as the fighting force in the field—what are some of the chief dangers and difficulties attending the movement for the extension of the registration area, and interfering, or likely to interfere, with the passage and proper enforcement of adequate registration laws.

First, and most ominous, is the tendency to allow undertakers to act for local registrars as subregistrars of deaths and issue burial or removal "permits" to themselves. The "permit" thus issued is no longer a permit, forming the most essential item of the registration machinery and insuring that the death must be registered by a responsible official before interment. It is a mere farce, and the very statement of "issuing a permit to oneself" should show its ridiculous character. In practice it seriously interferes with the function of the local registrar, because he can not know, before the body is disposed of, that the death has been properly registered; and undertakers acting as subregistrars will frequently fail to file certificates promptly and will not exercise as much care in securing satisfactory certificates as a well-qualified local registrar should. In such cases the latter can not prevent this by refusing a permit until a legal certificate of death has been filed.

Every facility, to be sure, should be afforded undertakers in complying with the necessary requirements of an effective registration law, and for this purpose the requisite number of local registrars conveniently located is very important, and also the plan of utilizing the nearest registrar as in the Ontario law. Yet the occasional complaints of "hardship," few of which are well-founded, should not be made an excuse for turning a registration system over to the undertakers neck and crop and expecting them to enforce it against their personal convenience. For it is undoubtedly easier and simpler to inter the body of a dead human being without taking the pains to make a legal record of the death, as is done in many of our states at present—one of them only across the Potomac from the capital of the United States—and any "red tape" in this matter, if compliance is to be secured, certainly requires a little attention on the part of somebody, and a penalty to compel such compliance. Who can better take this trouble than the man who forever removes the evidence of death and of the cause of death from the world? As a matter of fact, registration laws thoroughly enforced are a benefit to the undertaker's profession and will undoubtedly be recognized as such by all progressive funeral directors and licensed embalmers familiar with their practical operation in registration states.

The second difficulty is the ever-recurring interference of the old and thoroughly discredited county system of collecting returns. Satisfactory returns of births or deaths have never been collected through county officers (clerks, health officers, probate judges, etc.) in any state, as many times as it has been attempted to do so, and never will be, for the plan is inherently opposed to the essential requirements of registration. Yet it will take a vast deal of education to get the "county idea" out of the heads of legislators, especially in the southwestern and southern states.

The third difficulty lies in the weakness of the executive functions and financial powers of some state boards of health, to which are usually entrusted the administration of registration laws. Registration is not the showy side of sanitary work. It requires some money and it takes much time, patience, tact, and again tact, patience and time. It is not pleasant work, to many minds, for it requires much attention to details, and forever and forever the insistence that undertakers, physicians, registrars, shall understand and obey the law. And it may require backbone, when it is easy to connive at or ignore violations of the "letter" (and usually the spirit goes with the "letter") of the law, to insist that the plain requirements of the law be obeyed, or that prosecution follow. The individual who desires an exception to be made in his case may have political influence or at least have influential friends. And for all this trouble the sanitary official gets only figures for his pains, which are more or less valuable in proportion to his faithfulness to his duty to the state. He may also feel that he has helped to maintain the priceless vital records of the commonwealth. But it is not showy work, although it may demand as great persistence, ability and technical training as any or all of the other duties of the state health department.

Our state boards of health should be strengthened when weak, and they should have ample provisions for the necessary cost of registration of vital statistics—which is not excessive—when this duty is imposed on them. They should obtain the best ability possible to direct the registration work, and should support it firmly in the fearless, but uniform and equitable, enforcement of the law. If they can not obtain money for this purpose or command executive ability, they should retire from the field and seek to build up a bureau of vital statistics in some more favored department of the government. But it will usually be possible to secure the necessary means, and care should be taken that they are devoted to the fundamental requirement of better vital statistics, rather than diverted to more attractive but less essential lines of work. If vital statistics are in fact, and not as a mere theory, the foundation of sanitation, then one should insist on a good foundation before attempting much of a superstructure. This is better than to have a house all cupola, suspended in midair like Mahomet's coffin.

THE USE OF DIGITALIS IN PNEUMONIA.

THOMAS F. REILLY, M.D.
Professor of Applied Therapeutics in the Medical Department of Fordham University.
NEW YORK.

Much has been written, pro and con, on the use of digitalis in pneumonia. It is not my purpose to review the literature, which is as confusing as anything that can be found in medicine. I shall confine myself largely to a statement of the clinical results following the use of fairly large doses of the drug in this disease as it occurs in private practice. The therapeutic nihilism of the past decade has come to regard as the ideal method of managing pneumonia the do-nothing policy of treating symptoms as they arise. The enormous mortality rates following such a policy is sufficient reason for trying to do something better.

In this disease we have two general indications from start to finish: 1, to get rid of the toxins as far as possible, until Nature is able to furnish her antitoxin; 2, to sustain the heart and circulation, on which the brunt of the attack falls, until the danger is past. If we can accomplish these two results our patient will probably be saved. The only organs at our command to eliminate the toxins are the bowels, skin and kidneys. As in all intoxications, the first two of these should be stimulated to increased action. By proper manipulation and dosage we have in digitalis one of the best diuretics. It not only increases markedly the flow of urine but also, to some extent, the quantity of excrementitious matters.

As to the heart itself, the most important danger is the tendency of failure arising (a) from the action of the poison on the neuromuscular mechanism of the heart, (b) from granular degeneracy of the cardiac muscle under high temperature, probably of minor importance, and (c) from overloading and distention of the right ventricle, consequent on pulmonary obstruction, another factor of minor importance. Associated with this condition of the right side is the venous engorgement and a high degree of arterial anemia. This last fact tells again on the heart itself by diminishing the nutrition of the heart muscle from lack of proper blood supply through the coronary arteries. Now it is a well-established physiologic fact that digitalis slows the heart by lengthening the cardiac diastole and so rests the wearied cardiac muscle; but beyond this it also aids in the direct nutrition of the heart. the blood supply reaching it only through the period of diastole.

The wild claims of Petresco that he could abort pneumonia by large doses of digitalis have never been believed, and have always been quoted in derision of the digitalis treatment. I do not believe that all pneumonia patients can be saved by this drug, but by the judicious use of digitalis we can frequently manage to keep our patient's pulse under 100 per minute. The elaborate statistics published by the Massachusetts General Hospital show that with a pulse under 100 the disease is seldom or never fatal.

It is all right to say: "Do nothing for mild cases—the patients will get well under Nature's care"; but who can say that the patient in the mild case will not get worse and the heart fail? The text-books say: "Give digitalis, when the heart begins to fail." Then it is too late. It requires from twenty to thirty hours before this drug gets a complete hold on the heart. The experiments of Brunton and Cash, made many years ago and confirmed often since, go to show that in the presence of high temperature the effects of digitalis on the vagus are much less than in normal conditions, but its action on the cardiac muscle itself is not interfered with, so it does not affect the heart so much by its inhibitory action as by direct action on the muscle. As to the dangers of digitalis medication, aside from a marked arrhythmia after the crisis, which is quite often characteristic of the disease itself, I have personally seen no evil results. The symptoms of digitalis intoxication are not usually alarming and can easily be overcome by lessening the dosage.

In preparing any statistics, I am well aware that, in the first four decades of life, croupous pneumonia does not have a very high mortality; certainly after the first year and until the twentieth year the mortality is very low. It is at this time that we are not likely to have complications. The kidneys are healthy and the toxins are readily thrown off. After forty years comes the really severe test of any treatment. We should not properly include in our statistics cases associated with advanced organic disease of some vital organ, because in such cases the lethal issue is due perhaps as much to the organic disease as to the pneumonia, and no remedy could possibly alter conditions.

Bronchopneumonia, although its clinical picture is generally different, is quite often due to the same organism and the general indications of support and eliminations are the same. It is, however, according to statistics, a much more fatal disease. I have collected the statistics separately and together. There was a total of 150 cases. Of these 126 were of the lobar variety; there were twenty-four cases of bronchopneumonia; the ages varied from 2 weeks to 80 years. The fatal cases occurred at the following ages: In lobar pneumonia, at 48, at 60, at 72 and at 80; in bronchopneumonia three cases at 3 years of age, one with asthma and one with measles, and one case (tuberculous) at 75. There were four deaths in each series, a mortality rate of 3.17 per cent. for the lobar variety and 16.6 per cent. for bronchopneumonia, a general mortality rate of 5.53.

The treatment consisted (a) of the uniform administration of quite large doses of some reliable preparation of digitalis, usually the fluidextract, as soon as the diagnosis was made; (b) elimination of the toxins by means of simple diuretics and diaphoretics, the vegetable potash salts, and spiritus ætheris nitrosi; and (c) the use of strychnin, caffein, etc., as stimulation was required. As to the dosage, it must vary with the individual case. A very young adult generally receives three minims of the fluidextract every three hours steadily for days, increasing if the pulse increases markedly; a child of 1 year received from two to four minims of the tincture, or one-half drop of fluidextract, every three or four hours as the case demanded.

These statistics, small in number as they are, represent the wide variations of private practice and cover a period of ten years, so that they do not represent any special season, which often makes a marked difference in our mortality rates. While it is without doubt true that many of these patients would have recovered without any medication, I feel satisfied that a goodly number would have perished without it.

204 West One Hundred and Forty-first Street.

Danger from Saline Injections in Cholera.—E. J. O'Meara, in the *Indian Medical Gazette*, states that the vitality is so depressed in cholera that there is the greatest danger of cellulitis from saline injection into cellular tissue, no matter how carefully the operation is performed.

HEMORRHAGIC DISEASES OF THE NEWBORN.

HENRY ENOS TULEY, M.D.
Professor of Obstetrics, Medical Department, University of Louisville.
LOUISVILLE, KY.

Newborn babies are specially prone to develop hemorrhages, and because of the indefinite knowledge to-day of the true pathology of the condition, the symptom-complex is now called in general terms, "hemorrhages of the newborn." Formerly an attempt was made to describe each case according to the location of the hemorrhage, in this way having a number of terms descriptive of the same general underlying disease. King, Genrich and Runge, quoted by Koplik, state that hemorrhagic disease in the newborn occurs about once in a thousand cases. Shukowsky's estimate of twenty-nine in thirty thousand agrees with this statement.

ETIOLOGY.

The etiology of the condition is obscure; but in view of the fact that fever is a prominent symptom in most cases, the general consensus is that the most frequent causative factor is a general septic infection. The newborn develop sepsis easily and the entrance of the offending organisms to the system may be at many points, the gastrointestinal tract, the mouth, the genitourinary tract and the umbilicus being the most frequent portals. Gartner asserts that he has found bacilli in the feces in cases of melena, proving his theory that this form of hemorrhage is a coccal sepsis. In Winckel's disease, a condition closely similar, streptococci and bacilli have been found in various organs and the blood. The changes which occur in syphilis, which has been named as a cause, are in the blood vessels, rather than in the blood itself.

Lambert, in the report of his most interesting case, gives the following bacteria which have been isolated in reported cases: *Staphylococcus, Pneumococcus, Bacillus pyocyaneus, Bacillus coli, Bacillus typhosus and Bacillus diphtheriæ.*

Among the other causative factors have been mentioned prematurity, atelectasis, deformity of the heart, persistent foramen ovale or ductus arteriosus, ulcer of the stomach and intestine, the latter due to a venous stasis, followed by a thrombosis; fatty degeneration of the arterioles; extreme delicacy of the blood vessels; congenital obstruction of the portal venous system; congestion from pulmonary, cardiac or hepatic disease; excessive secretion of gastric juice resulting in partial digestion of the mucosa of stomach and intestine, congenital hemophilia and the great changes taking place in the circulation incident to birth.

LOCATION.

Hemorrhages in the newborn may take place from any organ and the hemorrhage may occur before birth or subsequently. When postnatal, it usually occurs within the first three days after birth.

In Dr. Townsend's fifty cases, quoted by Rotch, he gives the following location of the hemorrhages:

Intestine	20
Stomach	14
Nose	12
Mouth	14
Umbilicus	16
Ecchymosis in skin	21
Scratch of skin	1
Cephalic hematoma	3
Meninges	4
Abdominal cavity	2
Pleural cavity	2
Lung	1
Thymus gland	1
Gastroenteric tract, nose, and umbilicus accompanied by ecchymosis of skin	3
Gastroenteric tract alone	19
Umbilicus alone	3
Ecchymosis of skin alone	6

Holt gives Ritter's statistics in 190 cases as follows: Hemorrhage from the umbilicus, 138 (umbilicus alone, 97); intestines, 39; mouth, 28; stomach, 20; conjunctivæ, 20; ears, 9.

I have seen one case of hemorrhage into the suprarenal gland,[1] a number of cases of cephalic hematoma, both single and double, and the case shortly to be reported, of melena, or hemorrhage from the stomach and intestine. In the case of hemorrhage in the suprarenal capsule, the right suprarenal gland was distended to the size of an orange, with blood, and blood-clots were found behind the kidney and in the free peritoneal cavity. The diagnosis was not made in this case during life, the most prominent symptom being a profound jaundice. The hemorrhage was found postmortem.

Hemorrhage from the gastrointestinal tract may occur independently of bleeding from any other organ, and is called melena. If from the mouth alone, the quantity of blood lost is usually small; if from the stomach, large quantities may be vomited or passed from the bowel in form of clots. As stated, it has been thought by different observers to be due to an ulceration of the mucous membrane, following septic emboli of its vessels, or digestion of the membrane by a hyperacid gastric juice, or to a general pyogenic septic condition.

Like the other forms, it usually occurs during the first three days, and with great variety as late as the ninth day. The child may first vomit some red blood, followed soon afterward by a coffee-ground vomit; or blood may first be noticed in the discharges from the bowel. The fact that the meconium is very dark in color may cause blood in the actions to be overlooked, unless it is passed in large clots. If passed in considerable quantity the napkin at the edge of the mass will be stained a reddish color; of if blood is suspected, a microscopic examination will reveal the blood corpuscles. It should be borne in mind, before a diagnosis of hemorrhagic disease is made, that the source of the blood may have been a fissured nipple, or blood from the nose which had been swallowed. I have seen one case which caused considerable uneasiness until it was finally decided that the source of the blood was a cracked nipple.

PROGNOSIS.

The prognosis in hemorrhagic diseases of the newborn varies according to the site of the bleeding. Taken as a whole the mortality is given by various authors differently; in Townsend's cases 62 per cent., and in another series of 709 cases 79 per cent.; Williams places it at 60 per cent. Holt states no observer has seen more than one-third of his patients recover.

The following history is given as illustrative of that form of hemorrhage known as melena:

Patient.—Child, iii-gravida. (First labor instrumental, occiput posterior, forceps rotation. Second labor normal but prolonged.) Third labor began at 12 midnight; birth at 1 p. m. following day. Vertex presentation; first position; mechanism and labor normal. Child female, weight 9 pounds 8 ounces; normal in every way; primary respiration prompt and normal; no cyanosis; nursed vigorously when put to the breast. An abundant supply of milk appeared on the third day.

Hemorrhage.—On the third day at noon the child vomited red blood, sufficient in quantity to stain its clothes through and through. Shortly after this a very large movement of meconium was passed containing red blood, very easily distinguished in the black meconium mass. The child was pale and blue around the nose; the pulse was weak and rapid; the child refused to nurse after vomiting blood, the nursing being discontinued after hemorrhage was reported. For two days vomiting of blood and hemorrhage from the bowels occurred, the latter profuse and passed in masses of clots.

---

[1] Arch. of Pediat., November, 1892.

Treatment.—After treatment with subcutaneous injection of gelatin solution, 2 per cent., described below, the child made a good recovery; at the end of the second week it had regained its birth weight and continued to thrive.

TREATMENT.

Different methods of treatment have been suggested by various authors. Koplik suggests the cold coil; ergotin, ½ to ¾ grain subcutaneously; Henoch suggests one drop of liquor ferri sesquichloridi in barley water, every hour; Williams suggests gallic acid, gr. 1, every three hours, oil of turpentine. m. 1, in mucilage every hour; extract of krameria, grains 2, every two or three hours, or an injection into the bowel of an infusion 4 to 5 ounces, and calcium chlorid to increase the coagulability of the blood.

The subcutaneous injection of gelatin employed in the case reported was followed by very prompt recovery. The English gelatin was used in this case, as the ordinary commercial gelatin has been found contaminated with the tetanus bacillus.

Two sterilizations of the gelatin are made in order to be sure that this organism is destroyed. An ordinary antitoxin syringe or aspirator, without too large a needle, can be used for the injection. The cellular tissue of the back can be used, the solution warmed and 20 c.c. can be slowly injected.

Weil[2] of Paris experimented in patients with hemophilia, in whom he was able to control the tendency to bleed for a certain time with the injections of fresh serum. He states that the "sera of man, the rabbit, horse and cattle have been found equally efficacious, although *in vitro*. the action of the human serum is more evident in correcting the disorder." He injects 30 c.c. under the skin, and suggests the use of diphtheritic serum, if fresh.

As long as there is any bleeding from the stomach food can not be given in this way, but it can be given by nutrient enemata.

After writing this paper I saw another case, very similar to the one reported, except that the hemorrhages began on the second day and were more profuse and frequent. The gelatin solution was used subcutaneously every three hours and this child recovered, although a very grave prognosis was given.

This treatment was advised in a third case, the attending physician consulting with me in regard to it over the telephone, and this patient also recovered, though the physician thought that the child would die.

2. Internat. Clin., series 17, iv.

Tuberculosis and Discharged Prisoners.—Dr. J. B. Ranson, physician at Clinton Prison, at the recent meeting of the New York state conference of charities and correction, spoke of the danger of discharged prisoners infecting others with tuberculosis. He says that there are annually discharged from the penal institutions of the United States over 100,000 prisoners, and from the penal institutions of the State of New York 12,000. Of this number a large percentage are in some degree infected. These become scattered throughout the country, living under unsanitary conditions, regardless of the care of their person, and often indulging a feeling of hostility to society. The possibility of infection which this vast army may possess and its responsibility for the prevalence of this disease in our large cities and towns can not be estimated.

Clinical Notes

DOUBLE SUPPURATIVE PAROTITIS COMPLICATING TYPHOID IN A BOY ELEVEN YEARS OLD.*

HOWARD CHILDS CARPENTER, M.D.
Assistant Pediatrist to the University Hospital.
PHILADELPHIA.

Patient.—T. P., aged 11, an Italian, was admitted to the University Hospital on Aug. 15, 1908. His father, mother and one brother were living and well. One sister had died, aged 15, cause unknown. The patient had never been sick before his present illness.

Present Illness.—He had been sick ten days, and in bed seven days before coming to the hospital. At first it was noticed that he stopped playing and would lie around the house most of the day. Later he complained of headache and general pains all through his body. He developed a severe diarrhea and became so weak he could scarcely move. He had no hemorrhage from the nose.

Physical Examination.—General: The patient was a well-developed boy with moderate wasting of the muscles and subcutaneous adipose tissue. The bony skeleton was well proportioned and the chest normal in shape. The patient's mental condition was decidedly dull; he was semistuporous but could be roused with some difficulty. His eyes were sunken and surrounded by dark rings. There was some ptosis of the upper lids, and the conjunctivæ were somewhat dry. The pupils were slightly dilated, equal, and reacted to light. The lips were dry and cracked; the mouth was kept open and the teeth were dry. The tongue was thickened, dry, fissured with a brownish-yellow coating, and the breath was offensive. The external lymphatic glands were not enlarged. There were no rose spots on arms, chest or abdomen. A slight Kernig's sign was present on both sides. The knee-jerks were absent. There was no ankle clonus, or Babinski. The leucocyte count was 9,600.

Heart: The apex beat was visible in the fourth interspace, 0.5 cm. to the right of the midclavicular line; there was also a diffuse impulse seen all over the precordium. Cardiac dulness extended from the right parasternal line to the left midclavicular line, and began above at the lower border of the second rib. The first sound at the apex was feeble. The heart's action was regular and slightly rapid, but no murmurs were audible. The second sound at the pulmonary area was moderately accentuated.

Lungs: The type of breathing was principally thoracic. Expansion was good, and slightly more marked on the right side than the left. Tactile fremitus could be felt normally over both lungs, and was more marked on the right side. Over both lungs breath sounds were normal, and vocal resonance was heard well everywhere. No râles were present. There was normal pulmonary resonance both anteriorly and posteriorly.

Abdomen: The abdomen was distended, particularly the lower half. There was some resistance to palpation, more on the right side than on the left. Slight tenderness was present in the region of the gall bladder. To percussion the abdomen was everywhere tympanitic. The spleen extended above from the eighth rib in the mid-axillary line to the edge of the ribs; and anteriorly as far as the anterior axillary line. It was not palpable. The liver reached from the fourth rib to the costal margin, in the mid-clavicular line. It could not be palpated.

Clinical Course.—Thirteenth day of Illness: Forty-eight hours after admission there was no change in the patient's condition except in the right upper quadrant of the abdomen. Here there was localized rigidity of the abdominal walls, with marked tenderness. There was a palpable mass, dull on percussion, in the region of the gall bladder, extending in length 6 cm. beyond the edge of the ribs in the mid-clavicular line.

---

* Presented at the Philadelphia Pediatric Society, Oct. 13, 1908.
* From the Service of Dr. J. P. Crozer Griffith.

and in width from the right parasternal line to just beyond the right mid-clavicular line.

Fourteenth Day: The mass had disappeared, but rigidity and tenderness still remained. The leucocyte count had increased to 22,000.

Fifteenth Day: The mass in the region of the gall bladder returned, and seemed even a little larger than it was before. Rigidity became more marked, and the mass was very tender to the lightest palpation. The leucocyte count was 20,600.

Seventeenth Day: The patient developed a swelling below, extending up slightly in front of the left ear, which was tender to palpation. There was no tenderness over the mastoid, and the auricle, which was red, did not stand out any more than the right. The leucocyte count was 28,800. The patient's general condition had improved. His spleen now extended 2.5 cm. below the edge of the ribs in the anterior axillary line. The abdomen was flat. The gall bladder was not palpable, and tenderness and rigidity in the right upper quadrant was subsiding.

Eighteenth Day: In twenty-four hours the left parotid became very large, the swelling extended upward as far as the top of the ear, and as far forward as the eye. There was comparatively little swelling posteriorly, but the swelling extended downward beneath the jaw. The swelling was very firm, tender, pitted on pressure, and showed elevation of temperature on palpation.

Nineteenth Day: In twenty-four hours after we had first observed the swelling of the left parotid, the gland on the right side became involved. The right parotid appeared similar to the left gland twenty-four hours previous. The leucocytes were 21,800.

Twentieth Day: There was enormous swelling of both sides of the face, largest on the left side, where it was most prominent in front of the ear; here the skin was shiny and very tense. There was some ecchymosis below the left auricle. The lobe of the ear was swollen, and had on it a large blister. The swelling and edema extended upward 1 cm. above the auricle; and below it was beginning to extend down the neck. Posteriorly the edema almost reached the middle of the occiput. There was no fluctuation. On the right side the swelling was almost entirely in front and below the ear. On both sides there was extensive inflammation of the tissues surrounding the parotids. The leucocytes were 21,400.

Twenty-first Day: The parotid on the left side appeared to be pointing just in front and below the ear. On the right side deep fluctuation could be felt below in front of the ear. Both abscesses were opened by Dr. C. C. Rush. From the left side two drams of pus were removed, and almost a dram from the right. This pus was examined bacteriologically and contained *Bacillus typhosus* and *Micrococcus pyogenes aureus.*

Thirtieth Day: The notes state that the patient was rapidly improving. His abdomen was soft and flat, the spleen could not be felt, and there was no tenderness or rigidity in the region of the gall bladder. He looked much brighter and talked intelligently. His pulse was very small and compressible, but regular and not rapid. His temperature had shown a daily range between normal and 102. It was almost invariably elevated after his dressing was changed. The swellings in front and above the ears had almost entirely subsided, but the abscesses were not much improved. The one on the left was very deep, extending more than an inch into the deep structures of the neck, uncomfortably near the deep vessels. The pus was thick and cream-colored and very offensive; about half an ounce was daily removed from the left side, and a dram from the right. The leucocytes had dropped to 7,000.

Thirty-first Day: The openings in both abscesses were enlarged on account of the retention of pus; the one on the left side, by an incision an inch long downward and forward; the one on the right by an incision half an inch long, posteriorly.

Thirty-third Day: Two sores about two and one-half inches were discovered behind each ear. The one on the right side was a necrotic ring the size of a quarter. Cultures made from this area on bile medium in an endeavor to isolate the typhoid bacillus were negative. On the right side, although there was no break in the surface of the skin, the area was reddened, indurated, and had a softened center. A small incision was made, but no pus obtained. Leucocytes, 6,500.

Thirty-ninth Day: An area of swelling and induration was noticed to have developed below the outer angle of the left eye, about one and a half inches in diameter, with swelling of the left eyelid. In two days the inflammation of the left cheek had subsided.

Forty-fourth Day: The parotid abscesses were doing splendidly. The sore over the occipital region on the right side continued to deepen until the bone on this side was exposed. The edges of the wound were healthy. An air-cushion was kept constantly under the patient's head, and he slept on his side, so that there was little pressure brought on that region. The same day an abscess on the side of his right hip was opened and quite a little pus removed.

Fifty-first Day: The openings of the parotid abscesses were completely healed. The sore in the left occipital region was almost well and the one in the right occiptal region was healing rapidly; there was no longer any exposed bone.

Urine: On the twelfth and twenty-ninth days the urine contained a trace of albumin and a few hyaline and pale granular tube casts. The Diazo reaction was positive. On the twenty-ninth day the urine contained a large number of pus cells. On the forty-fifth and sixty-seventh days the urine examination was normal.

Blood: On the thirteenth day the blood gave a strongly positive Widal reaction. On the thirteenth day the hemoglobin was 81 per cent. On the thirty-ninth day the hemoglobin had dropped to 48 per cent. and the red blood corpuscles were 3,040,000. On the seventieth day the hemoglobin was 55 per cent. and there were 4,140,000 red blood corpuscles.

1805 Spruce Street.

DERMOID OVARIAN CYSTS OF UNUSUAL SIZE.*

EDWARD N. LIELL, M.D.
Gynecologist to St. Luke's Hospital.
JACKSONVILLE, FLA.

The following cases of dermoid ovarian cyst are of interest, not alone because of their enormous size (they weighed, respectively, 42, 39 and 32 pounds), but because of the singular fact that all three were of the left ovary.

Usually cysts of this character are small in size and of slow growth. Not infrequently they develop rapidly, attaining enormous size; rarely they become purulent, with associated fever, as instanced in one of my cases. Dr. T. Gaillard Thomas, in his "Diseases of Women," says that "dermoid cysts rarely grow larger than an adult head."

As to the genesis of these growths, the fact that they have been discovered in fetal life shows that the ovum possesses all the requisites for the development of the many structures present in dermoids, such as bone, cartilage, skin, membrane, hair, teeth, etc. Furthermore, as other ovarian cysts are almost invariably multilocular in character, it might be suggested here that dermoid ovarian cysts are perhaps originally multilocular also, the walls of smaller cysts being eventually compressed into the wall of the common cyst. Regarding the teeth, one text-book on surgery ventures the assertion that these are never perfect and can not be absolutely identified as incisors or molars. The specimen obtained in Case 1 proves the contrary.

The history, in brief, of these three cases is as follows:

---

* Read before the Southern Medical Association Section on Surgery, Atlanta, Ga., Nov. 10-12, 1908.

Case 1.—*Patient.*—Mrs. G., aged 42, had had three children. At the time she was referred to me, two years ago, she had considerable dyspnea as a result of abdominal distension and pressure, the growth reaching from the pubes to the ensiform cartilage. Her physical condition was frail, and her general condition much debilitated. On examination a diagnosis was made of ovarian cyst, about the size of a football. Immediate operation was advised, but refused. Ten days later dyspnea was so marked that, to induce relief—the patient still refusing operation—I was obliged to tap the cyst, evacuating through a trocar about one quart of light chocolate-colored fluid containing a few strands of hair. The character of the cyst was evident. As a result, the patient consented to an abdominal section.

Operation.—Adhesions were numerous, to the omentum, intestine, uterus and bladder. As a preliminary to enucleation the major portion of the fluid contents was evacuated through a trocar, the sac and remaining contents being then more readily delivered. The walls of the sac were fully one-quarter of an inch in thickness; in the ligation of the pedicle, because of its unusual size, Chinese twisted silk was used. The weight of the sac and contents was 42 pounds. The fluid was light chocolate in color and of the consistence of glycerin, a portion of it being, however, of a cheesy nature; it also contained a considerable quantity of hair, loose and in bunches. To the inner wall of the sac was attached much skin, and also a portion of a maxilla; in the latter, five teeth were inserted, and four more were free, in all nine teeth, one incisor and eight molars. There can be no question here as to the character or identity of the teeth.

Case 2.—*Patient.*—Mrs. B., aged 64, married thirty-five years, slender and somewhat emaciated, was referred to me in July, 1905. She had been conscious of a gradual enlargement of the abdomen for two years. In this case also a diagnosis of left ovarian cyst was made.

Operation.—The condition proved to be a dermoid cyst of the left ovary, the fluid being milky-yellow, somewhat oily in character. A quantity of hair and four teeth were also found, two of the teeth being attached to a portion of the sac wall. As in the previous case, because of the thickness of the sac wall, the same method of ligating the pedicle was pursued. The weight of the sac and contents in this case was 32 pounds.

Although this patient also made a good recovery, yet at one time, about sixteen days after operation, there was a suspicion of ileus, probably due to some slight adhesion about the pedicle; for several days some flatulent local distention existed.

Case 3.—*Patient.*—Mrs. H., aged 68, widow, was operated on by me at St. Elizabeth's Hospital, New York City, in 1895, while I was visiting gynecologist to that institution. Her condition was a treacherous one; she had, at the time of operation, a temperature of 103 and pulse 118, the result probably, of an injury by a fall a short time previously. Although markedly emaciated, she yet possessed unusual vitality. A diagnosis of left ovarian cyst, inflammatory in character, was made in her case. She came to me fully prepared to take the consequences of any surgical interference.

Operation.—This developed a suppurating dermoid left ovarian cyst, with numerous adhesions, which, however, were separated without apparent injury to other viscera. This cyst contained a fluid of a fatty, purulent, dark yellow nature. The usual accompaniments of hair, skin, and several teeth were found. Its total weight was 39 pounds.

140 West Monroe Street.

Infant Mortality.—J. Ullman (*Buffalo Medical Journal*), states that the mortality of infant life is appalling. It is due, he declares, to the ignorance of the mother and is greatest in proportion to the condition of poverty and the density of population. It has been designated as the "slaughter of the innocents" and still by educating the mother in cleanliness and the proper feeding of babies many an infant can be saved. "A helpless infant is entitled to milk that gives, not takes life."

New and Nonofficial Remedies

The following articles have been tentatively accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in the proposed annual, "New and Nonofficial Remedies." Their acceptance has been based largely on evidence supplied by the manufacturer or his agent, but to some extent on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before final acceptance and publication in book form.

The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that so far as known it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

(*A list of all accepted articles is published on an advertising page of* The Journal *in the first issue of each month.*)

(*Continued from Vol. LI, page 2161.*)

AMMONIUM HYPOPHOSPHITE—*Ammonii Hypophosphis.*—$NH_4H_2PO_2 = 82.46$.

Ammonium hypophosphite may be prepared by double decomposition between aqueous solutions of barium hypophosphite and ammonium sulphate. The liquid filtered from the precipitate is evaporated to dryness and the ammonium hypophosphite extracted from the residue with hot alcohol.

Ammonium hypophosphite occurs in irregular hexagonal tablets which melt without decomposition and at a higher temperature give off water and spontaneously inflammable hydrogen phosphide. According to H. Rose, ammonia, NH_3, escapes first. The compound is less soluble in water than the potassium salt, but is very soluble in absolute alcohol.

The aqueous solution should be neutral or slightly acid to litmus paper, and on gently heating with potassium hydroxide T. S evolve ammonia. The diluted aqueous solution slightly acidulated with diluted sulphuric acid, yields, with silver nitrate test solution, a white or brown precipitate, which rapidly turns black, owing to the separation of metallic silver. With copper sulphate test solution, after addition of dilute acid and on gentle heating, a reddish brown precipitate is formed. When the aqueous solution of the salt (1 in 20), acidulated with hydrochloric acid, is added, drop by drop, to an excess of mercuric chloride test solution, a white precipitate of mercurous chloride is formed. On further addition of the hypophosphite solution in excess, the precipitate becomes gray from reduction to metallic mercury.

The solution in water should give not more than a faint turbidity on the addition of barium chloride test solution nor on the addition of diluted sulphuric acid. A solution of 1 Gm. ammonium hypophosphite in 10 Cc. water should not be alkaline toward phenolphthalein T. S.: to render this solution alkaline should not require more than 0.4 Cc. normal potassium hydroxide V. S. The chloric acid should not respond to the U. S. P. Time-limit Test for heavy metals. If 5 Cc. of the aqueous solution of the salt (1 in 10) be measured into a beaker containing 3 Cc. of nitric acid, diluted with about 10 Cc. of water and evaporated to dryness on a water bath, the residue should not respond to the U. S. P. Modified Gutzeit's Test for arsenic.

Action and Uses.—Ammonium hypophosphite exhibits the actions of its constituents. It is used as stimulating expectorant, "alterative," and "resolvent" in diseases of the respiratory mucosæ, particularly in the later stages of acute bronchitis and laryngitis, and in chronic catarrhal conditions. Like other hypophosphites, it is said to be contraindicated in phthisis.

Dosage.—0.13 Gm. (2 grains) every 2 or 3 hours.

Proprietary Preparation:

GARDNER'S SYRUP OF CHEMICALLY PURE HYPOPHOSPHITE OF AMMONIUM.—*Syrupus Ammonii Hypophosphitis (Gardner).*—A syrup containing 3.33 Gm. ammonium hypophosphite in each 100 Cc. (16 grains in each fluidounce).

Action, Uses and Dosage.—See ammonium hypophosphite.

DIGESTIVE FERMENTS.

Under this general head will be described the several digestive ferments accepted for N. N. R.

Valuation of Ferments: Qualitative tests for the activity of ferments can be easily applied, but such qualitative results have very little importance. Quantitative results also are important only in so far as they permit comparison with other ferments; and for this purpose the minutest details of the methods must be accurately observed. After investigation, the Council has decided to employ the following quantitative methods in its work:

1. *Amylolytic Power:* (For diastases, malt and pancreas preparations.) The Council does not approve the methods which are based on the time of change from blue to red color given by iodin; or the time of disappearance of all color; or the amount

of sugar produced in a given time: but instead it has adopted as the standard the amount of starch that can be converted to colorless end point in 10 minutes, by a given weight of the product, working according to the details described. (THE JOURNAL A. M. A., July 11-08, p. 140, and Journal Am. Chem. Soc., 1908, Vol. 30, p. 798.)

2. *Proteolytic Power in Alkaline Media:* (For trypsin and pancreatic preparations.) The approved methods are based on the quantity of fresh fibrin or coagulated egg albumen, which is dissolved by a given weight of the substance, in a slightly alkaline medium and in a given time.

3. *Proteolytic Power in Acid Media:* (For pepsin and gastric preparations.) This is determined by the U. S. P. method.

4. *Milk-Curdling Power:* (For rennet and gastric preparations.) The method is based on the quantity required to coagulate 100 Cc. of milk.

Incompatibilities: Ferments are more or less rapidly destroyed by boiling, by alcohol, by many salts, by unsuitable reaction of vehicle, by putrefaction, and by proteolytic digestion. Solutions of ferments tend to deteriorate on keeping.

Ferments are generally destroyed by each other, and also during their sojourn in the stomach: little therapeutic action can be secured beyond this organ, at least under ordinary conditions.

Therapeutic Indications.—The digestive ferments are used outside the body to predigest food. They are often applied locally for the softening of dead tissues or the solution of false membranes. They are administered internally for the purpose of supplementing or replacing deficient or absent normal secretions. In such cases they should be administered in such manner and at such time as to secure the most favorable conditions for their action. Diastases should be given with the food or before the stomach becomes highly acid. Trypsin and other ferments which are to act in the intestine should be given near the end of gastric digestion with sufficient alkali to neutralize the acid of the gastric juice. In cases which present a nearly or quite total lack of acid in the stomach they may be given with alkali at meal time or soon after the meal is taken.

BISMUTH AND LITHIUM CITRATE (SOLUBLE), Wellcome Brand—Bismuthi et Lithii Citras Solubilis, B. W. & Co.—A "scale salt" of bismuth and lithium citrate containing 40 to 45 per cent. of bismuth (Bi) and 2.5 to 3 per cent. of lithium.

Bismuth and lithium citrate occurs in colorless scales, readily soluble in water. Its aqueous solution is acid toward phenolphthalein, but alkaline toward litmus T. S.

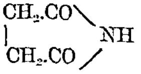
Tests. If 1 Gm. of the salt is warmed with 10 Cc. potassium hydroxide no ammonia is evolved (absence of ammonium compounds).

Action and Uses.—Recommended by the manufacturer as a convenient form of medication when the effects of both lithium and bismuth are desired, as in gouty dyspepsia.

Dosage.—0.13 to 0.3 Gm. (2 to 5 grains).

Manufactured by Burroughs, Wellcome & Co., London and New York. Not patented or trademarked.

MERCURY SUCCINIMIDE — Hydrargyri Succinimidum. — Mercury succinimide $((CH_2.CO)_2N)_2Hg = C_8H_8O_4N_2Hg$, is the mercuric salt of succinic acid-imide,



$$\begin{matrix} CH_2.CO \diagdown \\ \vert \qquad\qquad NH \\ CH_2.CO \diagup \end{matrix}$$

Mercury Succinimide may be prepared by dissolving freshly precipitated mercuric oxide in warm aqueous solution of succinimide and evaporating the mixture, which then deposits crystalline needles. (Schmidt's Pharm. Chemie, vol. II, pt. I, p. 482.) It may also be prepared by adding an alcoholic solution of succinimide containing a few drops of ammonia to an ethereal solution of mercuric chloride (Proceedings A. Ph. A., vol. 40, p. 1029). Mercury succinimide is a white crystalline powder, soluble in 25 parts hot water and in 75 parts of cold water, and in 300 parts of alcohol. It is very stable in solution. The aqueous solution is not affected by albumin. Mercury succinimide should be protected from light. Toward hydrogen sulphide and potassium iodide it reacts as an inorganic mercuric compound. Addition of sodium hydroxide to an aqueous solution of mercuric succinimide produces a yellowish-white precipitate, which on heating is reduced to metallic mercury. If mercuric succinimide is heated with five times its bulk of zinc dust, pyrrol is given off, which may be recognized by the red color which is developed when a pine shaving moistened with hydrochloric acid is held in its vapors.

The aqueous solution must be neutral and should not be affected by solutions of silver nitrate or egg albumin (absence of mercuric chloride and other mercuric salts).

On ignition it should volatilize completely, leaving no residue. If one gram is shaken with 10 Cc. of dry ether, the liquid filtered and the ether removed by evaporation, no residue should remain. If one gram is suspended in ether and hydrogen sulphide passed through the mixture for some time, the mercury succinimide will be decomposed, the mercury being precipitated as mercuric sulphide. If the ether be filtered from this precipitate, and evaporated, a residue of succinimide will remain which should have a melting point of 124-125° C.

Actions and Uses.—The succinimide of mercury has the action of other salts of mercury, but its solutions are said to be non-irritating. This preparation is used like other compounds of mercury in the treatment of syphilis.

Dosage.—The succinimide of mercury is used mainly by hypodermic injection, a 2.5 per cent. solution being employed. From ½ to 1 Cc. (8 to 16 minims) of this solution may be injected once daily. Mercuric succinimide may be given by the mouth in doses of 0.01 to 0.015 gm. (1/6 to 1/4 grain).

Non-Proprietary Preparation:

Tabloid Mercury Succinimide (Hypodermic) 0.013 Gm. (1/5 grain): Each tablet contains mercuric succinimide 0.013 Gm. (1/5 grain).
Prepared by Burroughs-Wellcome & Co., London and New York.

MORPHINE MECONATE.—Morphinæ Meconas.—Morphine meconate, $(C_{17}H_{19}NO_3)_2.C_7H_4O_7.5H_2O$, is the normal salt of morphine, $C_{17}H_{19}NO_3$, and meconic acid, $H_2(C_7H_2O_7)$, a dibasic acid obtained from opium.

Morphine meconate may be prepared by dissolving 10 Gm. crystallized meconic acid in 60 Cc. warm water, adding gradually 24 Gm., or sufficient crystallized morphine alkaloid to produce a neutral solution and evaporating to dryness at a temperature below 80° C. (176° F.). (Hager, 1903, vol. 2, p. 403.)

Morphine meconate occurs in minute colorless crystals or a yellowish white powder, soluble in 34 parts of water, also soluble in alcohol. It contains 66.3 per cent. anhydrous morphine.

Action, Uses and Dosage.—The same as other salts of morphine.

Non-Proprietary Preparation:

Tabloid Morphine Meconate (Hypodermic) 0.088 Gm. (1/8 grain). Each tablet contains morphine meconate 0.008 Gm. (1/8 grain).
Prepared by Burroughs-Wellcome & Co., London and New York.

SULPHANILIC ACID.—Acidum Sulphanilicum.—Acidum Sulfanilicum (Pharm. Helvetica, 4 edit.).—Sulphanilic acid, $C_6H_4(NH_2)(HSO_3)$ 1:4, is para-amino-benzene-sulphonic acid.

Twenty-five Gm. colorless aniline are gradually added to 75 Gm. concentrated sulphuric acid in a 250 Cc. flask and the mixture warmed to 180-190° C. under agitation for about three hours or until a drop of the mixture dropped into a solution of potassium hydroxide no longer gives indication of the presence of aniline. *At the end of the reaction the mixture is poured* into 500 Cc. cold water which precipitates the suphanilic acid as a grayish crystalline powder, it is treated with animal charcoal and recrystallized from hot water (Hager 1, p. 116).

Occurs as colorless crystals slightly soluble in water, and insoluble in alcohol and ether. It is decomposed at 280-300° C. It effloresces in air. It is soluble in 182 parts water at 10° C. and in 166 parts water at 10° C. It is not altered by boiling alkali, but fusion with alkali decomposes it yielding aniline. Chromic acid mixtures oxidizes it to chinon. Permanganate oxidizes it to *azo-benzene-sulphonic acid and an excess of this* reagent to carbon dioxide, sulphuric acid ammonia and oxalic acid. The cold saturated solution is not altered by hydrogen sulphide or barium chloride, but boiling with alkali should produce a visible change (Ph. Helvetica, iv, p. 18). One Gm. of the powdered acid treated with 3 Cc. zinc chloride solution should not be darkened. It should leave no residue on ignition (Ph. Helv.).

Uses and Dosage.—Internally (of doubtful value) in chronic catarrh of the respiratory mucosæ, 0.5 to 2 Gm. (10 to 30 grains) three times a day. It may be rendered more soluble by sodium bicarbonate. Its most important use is in Ehrlich's diazo-reaction for typhoid urines.

Proprietary Preparation:

SOLOID NIZIN.—Tablets, each of which contains 0.13 Gm. (2 grains) *of zinc sulphanilate.*

Actions and Uses.—Soloid Nizin is said to be an astringent and antiseptic. It is said to be useful in gonorrhea, in conjunctivitis and other eye affections.

Dosage.—One to three in 30 Cc. (one fluidounce) of water for urethral injection. One in 60 Cc. (2 fluidounces) for an eye lotion.

Prepared by Burroughs, Wellcome Co., London and New York.

(To be continued.)

Recurrences of Ectopic Pregnancy.—A. Chueco reports in the *Semana Medica*, Sept. 17, 1908, seven cases of recurring tubal pregnancy. It is remarkable, he says, how the second ectopic pregnancy runs the same kind of course as the first, either comparatively normal or tempestuous. He urges the necessity for examining the other adnexa when operating for an ectopic pregnancy. Gonorrheal infection does not seem to have anything to do with the abnormal localization of the ovum: its influence is rather against its inception of an extrauterine pregnancy, as the ovum can become imbedded only in sound tissue, and consequently an inflamed mucosa has a tendency to protect against abnormal location of the ovum. He warns against attempting to remove the placenta.

THE JOURNAL OF THE
AMERICAN MEDICAL ASSOCIATION

103 DEARBORN AVENUE . . . CHICAGO, ILL.

Cable Address . . . . "Medic, Chicago"

Subscription price . . . . . Five dollars per annum in advance

[*For other information see second page following reading matter*]

SATURDAY, DECEMBER 26, 1908.

[The large amount of space occupied by the index this week makes it necessary to omit some departments and to curtail all.]

THE INDEX.

For some years we have been supplying with each volume of THE JOURNAL an index of unusual scope and one on which, of necessity, much thought and labor are expended. When it is realized that in the present index the number of titles and authors alone exceeds 26,000, a large percentage of which are referred to more than once, it does not require any technical knowledge to appreciate the mere mechanical difficulties involved. When it is also borne in mind that the arrangement, grouping and combining of these thousands of titles is not work that can be done mechanically by filing clerks, however intelligent, but requires the individual attention of those possessed of medical training, the reason for our question in an editorial last July, "Is it worth while?" becomes apparent.

Our readers' answer to the question — unequivocally and overwhelmingly in the affirmative — was both astonishing and pleasing. Replies poured in from all over the country and within a short time over 700 had been received. All but eleven were favorable, some writers even going so far as to state that this was the most important feature of THE JOURNAL. The response left no doubt in our minds as to the advisability or importance of continuing this department.

There seems to be some confusion as to the distinction between the three departments of the index—the "General Index," the "Index to Subjects" and the "Index to Authors"—particularly as to the first two. The "General Index" is simply an index to matter which has appeared in THE JOURNAL and differs in no way (except size) from that of any other medical publication. The "Current Medical Literature Index to Subjects," on the other hand, is an index, by titles and subjects, of articles which have appeared in the leading medical journals of the world (including THE JOURNAL), and is entirely distinct from THE JOURNAL index proper. THE JOURNAL page on which each may be found is given, and if an article has been abstracted that fact is indicated by "ab" after the page number. The "Index of Authors" includes all the authors of articles which have appeared in other publications as well as in THE JOURNAL.

These facts are fully explained in the introductory paragraphs on the first page of each department of the Index, but we mention them here because we have learned from our correspondence that these explanations are not read so carefully as they should be.

The Index is reprinted as a separate pamphlet, with the itemized lists of articles that have appeared in other periodicals as they have been published in THE JOURNAL week by week. This book is called the "Guide to Current Medical Literature" and it is reprinted in this form to facilitate reference, without the necessity for handling a bound volume or loose copies of THE JOURNAL. If its convenience and the scope of its usefulness were more generally understood the demand for this "Guide" would undoubtedly be much in excess of what it now is. Reduced to plain terms, it means that in it THE JOURNAL furnishes an index medicus of the world's literature that is complete and exhaustive enough for all ordinary purposes.

THE THYMUS GLAND IN EXOPHTHALMIC GOITER.

Of late years the treatment of exophthalmic goiter has received a marked degree of attention from clinicians and surgeons alike. The results of serum therapy have been favorable in a considerable series of cases, but so great has been the success of surgical treatment that the tendency has become rather widespread to advise operation in all patients not relieved by medical aid and in many without ever giving the newer therapeutic measures a trial. That this may prove in some instances a most unwise procedure is strongly suggested by some recent German publications.[1]

Capelle has found the presence of an enlarged or persistent thymus a frequent occurrence at autopsy on patients developing "delirium cordis" and dying within twenty-four hours after operation for exophthalmic goiter—so frequent, indeed, that in the absence of other positive findings it assumes considerable etiologic importance It has been customary to assign such deaths to toxemia consequent on absorption of perverted thyroid secretion, but instances are cited of hasty exitus following simple ligation of the arteries without undue manipulation of the gland, in which cases acute hyperthyroidism alone manifestly could not be the causative factor. The relation of persistent thymus to sudden death, especially following surgical operation, is not a recent observation; the so-called thymus death has been recognized for years. The frequent association of enlarged or persistent thymus with exophthalmic goiter has been known for at least a decade; attention was called to it by Bonnet, Hektoen, von Hanseman and others, Ord and

---

[1] Capelle: Ueber die Beziehungen der Thymus zum Morbus Basedow, ii, Beitr. z. klin. Chir., Tübing., June, *1908*, lviii, 353-393; also Ein neuer Beitrag. zur Basedowthymus, München. *med.* Wchnschr., No. 35, Sept. 1, 1908.

Mackenzie asserting that the gland was enlarged in all cases of Graves' disease examined by them; but its presence in 80 per cent. of Capelle's series of over sixty fatal cases certainly gives food for thought.

The need for more careful examination of patients is apparent. Marked cardiac disturbance or evidence of the status lymphaticus, such as enlargement of the spleen and other glandular organs, hypertrophy of the adenoid tissue of nose and throat or hypoplasia of the genitalia, should make one suspicious. Careful percussion of the manubrium and upper chest may do much to establish a diagnosis which may be confirmed by the radiogram.

Is persistent thymus a contraindication for operation in exophthalmic goiter? This point remains to be established. The condition was a frequent finding in a considerable series of fatal cases: it may or may not have been present in a like number of successful ones; hence the need for more thorough investigation—*intra vitam* and preoperative. In analyzing cases of surgical cures the possibility of postoperative atrophy of the gland must, of course, be considered. Should it prove true that persistent thymus is rare in successful cases as it has been shown to be frequent in fatal ones—the inference is plain. On the other hand, if the condition is as common in one class as the other, even then the degree of thymic enlargement and the effect of feeding thymus preparations on the goiter symptoms, especially the tachycardia, may prove of prognostic value.

PSYCHOTHERAPY AND RELIGION.

The interest recently manifested by the church in psychotherapy may result in immense benefit, or in immense detriment, according as it is wisely or unwisely guided. As American, French and German psychologists have shown, psychotherapy benefits by employing mental forces which sometimes, indeed, run through religious channels and respond only to a touch which the subject recognizes as consecrated; yet these, if not controlled by some religious faith, may be utilized as well by the materialist as by the wild fanatic or the devout churchman. The "consolations of religion" are full of peace and hope—to those who can receive them. Thus they bestow that very condition of quietude and relaxation which releases the unconscious mind from the control of the conscious. This effect flows, not from the verity of any particular religious creed, but from the faith and reliance which the believer reposes in it. On the other hand, those not influenced by any religious tendency can obtain similar results through other means and forms of mental healing. Indeed, it is to be recollected that the extraordinary cures recorded by Drs. Bramwell, Bérillon and other physicians, as well as by certain clergymen, more especially, perhaps, in cases of insomnia, neurasthenia, hysteria and chronic alcoholism, are attributable chiefly to the skill of these men as psychologists.

The necessity for a campaign of education among laymen in regard to scientific psychotherapy, with a view to saving them from the "exaggerations and errors of the healing cults," is urged by the Rev. Chauncey J. Hawkins,[1] who asserts that people must be brought to regard psychotherapy as a scientific practice rather than a religious observance. The study of psychology and psychotherapy as a science, not as a cult, by the clergy is deserving of every encouragement. They should recognize that the cures effected by them are accomplished by calling into action those forces of which the subconscious mind is an unplumbed reservoir. In order to release these forces for their work the patient's tense will must be relaxed into absolute passivity and non-resistance. It is the conscious mind which forms the barrier that ordinarily restrains these reserve forces, and they are available for practical purposes only when the influence of the conscious mind is removed. Next to hypnotism, religious faith is without doubt one of the most powerful influences for removing this inhibiting influence of the conscious mind. When control has been gained of the reserve forces of the unconscious mind and they have been turned into the proper channels, the next step in subduing functional nervous disorders is to unify the forces of the subconscious with those of the conscious mind.

Further investigation by psychologists is needed to assay the proportions of truth and falsehood in the various modern attempts at mental therapeutics—as "faith cure," "animal magnetism," Eddyism, mental healing, divine healing—and to give them their proper valuation before the world. While it may be presumed that psychotherapy has but a limited sphere of usefulness, its application being restricted to functional nervous disorders, we must recognize the fact that the subjective or unconscious mind underlies all human nature; we must learn its powers and the methods by which they may be drawn forth. The public, moreover, is entitled to a full knowledge of the subject and the established psychologic principles underlying it. This the trained physician can furnish without being biased, either favorably or unfavorably, in regard to any existing religious creed.

One point, however, must be insisted on: the incorrectness of the prevalent belief that the control of bodily conditions by mental influences and the converse has been reserved for the last decade or two to discover and utilize. There has never been a period in the history of medicine in which psychotherapy has not formed part of actual medical practice—more or less superstitious, perhaps, in keeping with the age. This association of empiric practice based on unknown principles with known and recognized superstition has tended in the past to make physicians of scientific tendencies skeptical of the value of mental therapeutics; and this disdainful neglect by the strongest element of the profession has in its turn left the field of mental therapeutics open for the occupation of the numerous irregular cults. The problem now before the profession is to restore psychotherapy to its true place without allowing it to usurp that belonging to other therapeutic methods.

Medical News

ILLINOIS.

Bars Publicity.—On the ground that newspaper publicity is foreign to the principles of ethics of the medical profession. the Madison County Medical Society adopted resolutions at its last meeting deploring the practice and requesting the publishers of newspapers to omit the names of physicians and their deeds from their columns.

Talk on Tuberculosis.—Under the auspices of the Monroe County Medical Society. Dr. James W. Pettit. president of the Illinois State Medical Society, delivered an instructive address to the laity of Waterloo, December 8. on the "Tuberculosis Problem," after which he addressed the society on "Medical Organization" and the "Ways and Means of Securing a Full Attendance at County Society Meetings."

Chicago.

Children's Hospital Benefit.—Miss Isadore Duncan's interpretation of "Iphigenia in Aulis," given for the benefit of the Children's Memorial Hospital and the Theodore Thomas Orchestra invalid fund, December 8, is said to have netted more than $10,000 for these charities.

Work of Milk Commission.—The milk commission of Chicago, of which Dr. A. Belcham Keyes is secretary, has issued a physician's order blank. on the back of which is a list of stock formulæ of milk for infants and a list of the milk stations where the milk may be obtained. The commission also issues leaflets on "Buttermilk Food for Infant Feeding," and "How to Take Care of the Baby." The latter leaflet is supplied in seven languages, and copies for distribution will be sent by the commission on application.

Communicable Diseases.—The chief medical inspector reports that during the week ended December 19, 744 cases were reported, a reduction of 115 from the preceding week. To this total, diphtheria contributed 210. 21 fewer; scarlet fever, 199, or 14 fewer; measles. 99, or 1 less; chickenpox. 46, or 1 less; pneumonia, 17, or 9 fewer; whooping-cough. 12, or 9 fewer; tuberculosis, 61, or 21 fewer; and minor contagious diseases, 26, the same as for the week ended December 12. At the close of the week there were 21 diphtheria patients in the isolation hospital.

Mortality of the Week.—There were reported to the Department of Health during the week ended December 19, 580 deaths, 43 more than for the preceding week and 12 fewer than for the corresponding week of 1907, the respective annual deaths rates per 1.000 being 13.95, 12.92. and 14.65. Impure air diseases caused 160 deaths during the week as compared with 186 in the corresponding week of last year. There were 22 fewer deaths from tuberculosis, 2 fewer from pneumonia. and 2 fewer from bronchitis. Pneumonia caused 90 deaths; heart disease. 60; tuberculosis, 50; violence (including suicide). 47; nephritis, 36; cancer, 35; acute intestinal diseases, 34; diphtheria. 23; scarlet fever and typhoid fever, each 12; measles and influenza. each 3, and whooping-cough, 1 death.

INDIANA.

Gift to Hospital.—Henry L. Wallace. Crawfordsville, has given $7.000 to the L. L. Culver Union Hospital for the maintenance of the Susan E. Wallace free bed.

Suggestive Therapeutist Found Guilty.—Charles Witty, said to be a graduate of the Weltmer school. Nevada. Mo.. who was tried in Vincennes for practicing medicine without a license. is said to have been found guilty and fined $25 and costs. He threatens an appeal.

Society Meetings.—The eighth semi-annual meeting of the Thirteenth District Medical Society was held in South Bend. November 18. Dr. Charles Stoltz, South Bend. was elected president; Dr. William Kelsey, Monterey, vice-president, and Dr. Jesse B. Porter, Elkhart, secretary.——At the annual meeting of Fort Wayne Medical Society, held December 1, the following officers were elected: President, Dr. Henry O. Bruggeman; vice-president, Dr. Carl Schilling; secretary, Dr. J. Clifford Wallace; treasurer, Dr. William P. Whery; and censors, Drs. Edward J. McOscar, Hermann A. Duemling and Samuel H. Havice. The society now has 108 active members, 2 honorary members and one non-resident member. The society has also established a sick benefit fund to be used for the relief of indigent members should necessity arise.——At the regular meeting of the Howard County Medical Society, held in Kokomo, December 4, the following officers were elected: President, Dr. Oliver P. Kemp, Center; vice-president, Dr. James O. Garr, Kokomo; secretary-treasurer, Dr. Will J. Martin, Kokomo (re-elected); censors, Drs. Nathaniel C. Hamilton, James W. Wright and Charles J. Adams, Kokomo, and delegate to the state medical society, Dr. J. McLean Moulder, Kokomo.——The Fort Wayne Academy of Medicine elected the following officers, November 19: President, Dr. Willis W. Carey; vice-president, Dr. Harold K. Mouser; secretary, Dr. Cecil C. Kimmel, and treasurer. Dr. Howard V. Blosser.——At the annual meeting of Wabash County Medical Society, held in Wabash November 25. the following officers were elected: Dr. Gilbert M. LaSalle, Wabash, president; Dr. George D. Balsbaugh. North Manchester. vice-president; Dr. Lawrence E. Jewett, Wabash, secretary-treasurer. and Drs. Snearly, Roann, Emma G. Halloway, North Manchester. and Perry G. Moore, Wabash. censors.——White County Medical Society met in Monticello, December 3. and elected the following officers: President. Dr. Madison T. Didlake. Monticello; vice-president. Dr. Arthur B. Cray, Monticello; secretary, Dr. Grant Goodwin. Monticello; treasurer. Dr. George R. Clayton, Monon; censors. Drs. Jesse P. Galbreth, Burnett's Creek, Horace R. Minnick, Idaville. and William A. Spencer. Wolcott; and delegate to the state association. Dr. Jesse P. Galbreth.——De Kalb County Medical Society reorganized at Auburn December 3, and elected the following officers: President, Dr. Verta M. W. Swartz. Auburn; vice-presidents. Drs. E. K. Schurtz. Waterloo, and Oswald F. Rudolph, Corunna; secretary-treasurer, Dr. Charles S. Stewart. Auburn. and censors. Drs. Jacob B. Casebeer, Auburn; Martin E. Klinger, Garrett, and William Shumaker, Butler.

IOWA.

Unlicensed Practitioner Fined.—In the case of W. L. Taylor, Des Moines, charged with practicing medicine in Iowa without a license, and sentenced to pay a fine of $500, the Supreme Court, on November 16. confirmed the decision of the lower court, and the fine stands. The defendant appealed on the statute granting immunity to original physicians who had practiced in the state previous to the law making them subject to examination by the State Medical Board. It was, however, shown that he had never applied for a license.

Societies.—At the annual meeting of the Second District Medical Society, held in Davenport, the following officers were elected: President, Dr. John F. H. Sugg, Clinton; vice-presidents, Drs. David N. Loose, Maquoketa, and John L. Klein, Muscatine, and secretary-treasurer, Dr. John V. Littig, Davenport.——At the thirty-eighth annual meeting of the Southeastern Iowa Medical Association, held in Burlington, November 19, the following officers were elected: President. Dr. J. Frederick Clarke, Fairfield; vice-presidents, Drs. J. H. Chittum, Wapello, and Clyde A. Boice, Washington, and secretary-treasurer, Dr. Edward F. LaForce, Burlington.

KENTUCKY.

Society Meetings.—At the meeting of the Muldraugh Hill Medical Society. December 10, in Louisville, a resolution was adopted petitioning the governor to appoint a member of the Kentucky State Medical Society as a member of the board of control in charge of the charitable institutions of the state.——At the annual meeting of Pendleton County Medical Society, held in Falmouth. Dr. Henry C. Clark. Falmouth, was elected president; Dr. Thomas C. Nichols, Morgan, vice-president; Dr. N. H. Ellis. Goforth, critic; Dr. P. N. Blackerby. censor. and Dr. William A. McKenney, Falmouth. secretary-treasurer.

Personal.—Dr. D. H. McKinley, Winchester, has been offered the position of assistant superintendent of the Eastern Kentucky Hospital for the Insane.——The following are the visiting staff for Riverside Hospital, Paducah. for December and January: Surgical, Drs. William J. Bass and James T. Reddick; medical, Drs. Charles H. Brothers and William T. Graves; obstetrical. Dr. Joseph B. Acree; genitourinary, Dr. T. J. Crice; and eye, nose and throat, Dr. Harry F. Williamson.——Dr. Jsoeph A. Sweeney, Louisville, is suffering from septicemia due to an autopsy wound.——Dr. William H. Wathen, Louisville, recently underwent an operation at St. Anthony's Hospital in that city.——The office of Dr. W. Boone McClure, Sherbourne, was burned by incendiaries November 9.

Appropriation for Milk Investigation.—The Jefferson County Fiscal Court has made an appropriation of $1.500 to defray the expense of an investigation of the milk supply of the city as regards the presence of tuberculosis. The work will be under the supervision of Dr. Cyrus W. Field, director of the laboratories of the University of Louisville, and Dr. F. T. Eisenman, state veterinarian. The court has already furthered the work of milk investigation by employing Dr. Letchworth Smith to make bacterial counts of the various market milks. Some of them showed a count of 75,000,000 bacteria per c.c., and all the samples examined showed a count far above the standard 10.000 per c.c. required by the milk commission for certified milk, except the milk under the control of the commission.

New Headquarters Opened.—The new headquarters of the Jefferson County Medical Society, on the seventh floor of the Atherton Building, Louisville, were opened December 14, Dr. George W. Crile, Cleveland, delivering the dedicatory address. The society has three rooms, one room used for a meeting-place which seats 250, and two smaller rooms, in which will be located the Jefferson Medical Library. In this library there are already more than 3.000 volumes, the libraries of the late Dr. J. A. Ouchterlony, David W. Yandell, and James W. Holloway, and current medical journals. The committee on permanent home of the society is composed of Dr. Lewis S. McMurtry, John G. Cecil, J. Morrison Ray and William Jenkins. Dr. McMurtry, in his address, called attention to the two epochs which had marked the year 1908 for the medical profession in Louisville, namely, the selection and equipment of a home for the society, and the merging into one, of the medical schools of the city.

MARYLAND.

New Hospital.—The Washington County Hospital Association has purchased acres in the northern suburbs of Hagerstown for $37.000, on which it is proposed to erect a hospital with barn and dairy building. An anonymous benefactor has promised a donation of $7,000 for the hospital.

Must Conform to Standard.—The attorney general of Maryland has rendered an opinion to the Maryland State Board of Homeopathic Medical Examiners to the effect that students applying to take examinations must hold diplomas from recognized homeopathic medical schools, and that those wishing to take examination from the regular medical board must have diplomas from a recognized regular medical school. The complaint has been made that the homeopathic board has passed individuals who had previously been rejected by the regular medical board.

Baltimore.

Memorial Meeting.—A meeting in memory of the late Dr. William Keith Brooks, head of the department of biology in Johns Hopkins University, was held December 6, at which addresses were made by Drs. Ira Remsen, William H. Howell, Henry M. Hurd, and others.

Alleged Abortionist Convicted.—Dr. Robert X. Giering, who was recently brought from San Francisco to stand trial for performing a criminal operation, is said to have been found guilty December 8, and to have been sentenced to six years in the state penitentiary. He had previously been fined $1,000 for a similar offense.

Faculty Changes.—The following changes have occurred in the faculty of the Baltimore Medical College: Dr. Robert W. Johnson has resigned the chair of principles and practice of surgery, and will be succeeded by Dr. Ridgeley B. Warfield; Dr. William E. Moseley has resigned the chair of gynecology and will be succeeded by Dr. William B. Perry. Both of the new appointees had previously been associate professors in the college.

Dr. Brush Honored.—Dr. Edward N. Brush, superintendent of the Sheppard and Enoch Pratt Hospital, was given a dinner at the Baltimore Club December 11, as an expression of the personal regard of his friends for him, in their appreciation of the great service he has rendered in the public and private care of the insane, and in celebration of his completion of thirty years of service in insane hospitals in New York, Pennsylvania and Maryland. Dr. G. Alden Blumer, Providence, R. I., presided, and among the speakers were Attorney General Bonaparte, President Ira Remsen of Johns Hopkins University, and Drs. George A. Pope and Charles K. Mills, Philadelphia, and Dr. William A. White, Washington, D. C. A cablegram of greeting from Paris from Dr. William Osler was read. Dr. Brush has been editor of the *American Journal on Insanity*; has been a prominent contributor to the literature of psychiatry; has been much interested in securing adequate legislation for the protection of the rights of the insane; has done much to uphold the medical profession, and as president of the Medical and Chirurgical Faculty of Maryland, has given valuable service to the plans for the erection of a permanent building for its use.

MASSACHUSETTS.

Fever Closes School.—South Lancaster Academy was closed by order of the health board December 8, on account of the prevalence of scarlet fever.

Bequests for College and Hospital.—By the will of the late Mrs. Grace M. Kohn, Boston, a bequest is made to Harvard University to endow a department of biologic chemistry, and $10,000 is bequeathed to the Massachusetts General Hospital.

Personal.—Dr. Thomas M. Stone, first assistant in the executive department of the City Hospital, has resigned and will be succeeded by Dr. White.——Dr. Eloise A. Sears has been elected a member of the school board of Waltham.——Dr. Arthur H. Davidson has been appointed examining physician of the street department, Boston.——Dr. William H. Briard, Brighton, has returned from a long tour in the south.——Dr. Charles W. Taylor, recently appointed a member of the board of health of Lowell, has been elected chairman of the board.

MICHIGAN.

Hospital Under Quarantine.—On account of an epidemic of scarlet fever in the University of Michigan Hospital, Ann Arbor, November 17, absolute quarantine has been established.

Illegal Practitioner Found Guilty.—In the case of Donald McDonald, a Presbyterian minister of Iron River for a number of years, charged at Menominee with practicing medicine without a license, the jury, on December 1, is said to have found him guilty, but sentence was deferred.

October Mortality.—During October, 3.202 deaths were reported to the department of state, equivalent to an annual death rate of 15 per 1.000 population. Diarrhea and enteritis of infants caused 374 deaths; violence, 215; tuberculosis, 191; cancer, 148; pneumonia, 112; typhoid fever, 102; meningitis, 16; diphtheria, 33; whooping cough, 25; influenza, 13; scarlet fever, 12, and measles, 11. As compared with September, an increase is shown in the deaths from tuberculosis, typhoid fever, scarlet fever, whooping cough, pneumonia, meningitis, influenza, cancer and violence. The number of deaths from the latter cause for the month was increased as a result of forest fires in the northern part of the state, as from Presque Isle alone, 24 deaths were reported. A slight decrease is noted for the month in measles and diarrheal diseases of children.

Dangerous Communicable Diseases in October.—The average number of persons ill with pneumonia, and the average of fatal cases was above that of recent months. There were 32 new cases of, and 192 deaths from, tuberculosis, the number of deaths being considerably greater than for the preceding month or the average for October. Typhoid fever was reported to be present in 192 localities, or 28 more than for the preceding month. Diphtheria was much more prevalent than in September, but slightly less prevalent than the average for October in recent years. The disease was reported in 72 localities, or 17 more than during the preceding month. Meningitis was less prevalent than in September, but more prevalent than for October in recent years, and of the 54 deaths which occurred from this cause, 13 were in Detroit. Whooping cough, measles and scarlet fever were much more prevalent than in September, but less prevalent than for the average for October. The latter disease was reported in 52 localities, or 17 more than for September. Smallpox was less prevalent in October than in the preceding month, and very much less prevalent than for the average for October in the preceding years. During the month, the disease was reported from only 8 localities.

MISSOURI.

Physician Fined.—Dr. Charles Hume, Columbia, is said to have been fined $80 in the Boone county court for writing an illegal prescription for whisky. The case has been appealed.

New Tuberculosis Sanatorium.—An ordinance has been passed by the council of Kansas City, appropriating $10.000 for the erection of a building to be devoted to the treatment of tuberculosis.

Personal.—Dr. Bernard H. Zwart, Kansas City, has been elected coroner of Jackson county.——Dr. Bennett C. Hyde has been appointed a member of the staff of the Kansas City General Hospital.

Individual Drinking Cups for School Children.—The school board of Eureka Springs has decided to provide the pupils with individual drinking cups in order to lessen the danger of communicating disease.

St. Louis.

Receipts from Tag Day.—As the result of tag day, which was held in St. Louis. November 28, $21,874 was collected for the hospitals in the city.

Antituberculosis Week.—The week of December 14 was made memorable in the work of the Antituberculosis Society by the concentration of effort to spread knowledge of how to combat the white plague. A lecture was delivered each evening in different parts of the city by the following speakers: Drs. Harvey G. Nicks, William L. Perry, Solon Cameron, Samuel P. Stafford, Robert M. Gallen and Emmett W. McBratney and Mrs. Philip N. Moore.

Contagious Diseases.—During the fortnight ended December 12. the sanitary division of the health department reported 354 cases of infectious diseases and 46 deaths, distributed as follows: Puerperal fever. 1 death; erysipelas, 17 cases, 1 death; diphtheria, 140 cases, 6 deaths; scarlet fever, 43 cases, 1 death; typhoid fever, 13 cases. 4 deaths; measles. 39 cases, 1 death; chickenpox, 28 cases; whooping-cough, 7 cases. and consumption, 67 cases. 32 deaths.

Fined for Practicing Medicine Without a License.—Max Joseph von Herzog. styling himself the "World's Prophet." is said to have been fined $200 and costs in the Court of Criminal Correction for performing the functions of a physician without a license to practice medicine. In his defense von Herzog claimed that he had not pretended to be a physician, and denounced medicine as a fraud, but the court held this to be irrelevant. The defendant's attorney gave notice of appeal.

Personal.—Dr. Henry C. Fairbrother. formerly professor of railway and military surgery in the medical department of St. Louis University. has been elected professional lecturer on medical economics in that institution. including medical ethics.——Dr. German A. Jordan. chief dispensary physician. has succeeded Dr. William B. Winn. resigned. as assistant health commissioner.——Dr. Roy L. Gleason, interne at the City Hospital, has resigned to accept a position in the United States Indian Service.——Dr. George W. Flinn has been appointed assistant physician at the insane hospital. and Dr. J. J. Burdick, Jr., assistant physician at the City Hospital.

NEW YORK.

Tuberculosis Pavilions Opened.—The new pavilions at the new tuberculosis hospital of Erie county, erected at an expense of $6.000, are completed and give accommodation for thirty-five additional patients.

Medical Staff Election.—The medical staff of Our Lady of Victory Infant's Home, West Seneca, has elected the following officers: President, Dr. Michael A. Sullivan; vice-president, Dr. L. G. Hanley; and secretary, Dr. Edward M. Tracy.

Milk Supply for Cities.—The state dairymen's convention, which met in Utica on December 9. discussed the supply of milk for cities. It was shown that if the cities were to have a clean milk supply the consumers would have to pay the bill. Professor Cook argued for fewer and better cows, better feeding and more select breeding. He said these would do more to eliminate tuberculosis than legislation, tuberculin and zealous boards of health.

New York City.

Boat School Open.—An outdoor day camp for tuberculous children will be opened on a ferry boat moored in the East River off Bellevue Hospital, where a school run on the plan of the country school will be held. From to 30 to 35 children can be accommodated, ranging in age from 6 to 15 years.

Disposal of Sewage.—The New York Merchants' Association has issued a book entitled "The Battle of the Microbes." The book is very exhaustive, but deals with the subject of disposal of sewage in terms easily understood by the layman. It will be widely circulated in all sections of the country for the purpose of spreading information in regard to sewage sanitation.

Higher Death Rate Among Women.—A comparative study of the statistics of 1368. which time marks the beginning of the entrance of larger numbers of women into industrial fields, with the records for the year 1907, shows that the death rate for women between the ages of 45 and 54 for the year 1868 was 17.69 per 1,000, as compared with 19.67 in 1907; between the ages of 55 and 64 the death rate in 1868 was 29.37, and in 1907, 38.43; for 65 years and over the rate for 1868 was 88.40, while for the year 1907 it was 97.30. From all diseases except tuberculosis the increase has been uniform. The diseases which showed this uniform increase were those most likely to be caused by sedentary employment. Dr. Guilfoy claims that the increase is due to the incursion of women into industry, conditions entirely alien to their lives forty years ago. Life insurance companies have long since recognized this condition and take account of it.

Milk Must Be Pasteurized.—After three years' study of the milk problem and practical experience in feeding babies, the New York milk committee on December 5, promulgated a formal statement in favor of pasteurization as the method of securing safety from tuberculosis and other milk-borne diseases. The declaration of the committee was in the following terms:

> During the past three years the attitude of the New York milk committee toward the use of pasteurized milk has been so frequently misquoted that we ask your attention to the following authoritative statement of its opinion and practices:
>
> The committee approves of the pasteurization of all milk which has not been produced under sanitary conditions, which has not come from tuberculin-tested cattle and cattle otherwise free from disease and which can not be supplied to the consumer with a sufficiently low bacterial content to offer safety from milk-borne infection.
>
> The committee approves of the pasteurization of milk when modified for infants' use in the home.
>
> The committee approves of all measures, individual. state or municipal, which will lead to the institution of sanitary conditions on dairy farms. The conviction has on two occasions led it to oppose measures directed toward the establishment of compulsory pasteurization of milk by the city or state authorities. on the ground that such measures would put the producers of direty milk on an equal footing with the producers of clean milk, and thereby postpone the institution of the desired sanitary reforms.

At the last meeting of the Board of Aldermen an ordinance was introduced for the better regulation of the milk traffic. This measure, if adopted, will prevent the sale in this city of milk and cream not pasteurized that comes from dairies where herds are not certified by the board of health to be free from tubercular disease. The certificates would have to be renewed monthly. The first two sections of the ordinance read as follows:

> Section 1.—On and after Jan. 1, 1909, no milk or cream shall be sold at retail or offered for sale at retail, in the city of New York, except as hereinafter provided, unless the milk or cream has been certified by the Department of Health as containing not more than 500,000 bacteria to the cubic centimeter.
>
> Section 2.—All milk and cream not from certified herds, or not conforming to the said bacterial standard, shall be pasteurized by exposure for at least twenty minutes to a temperature of 167 degrees Fahrenheit, or by exposure for at least thirty minutes to a temperature of 158 degrees Fahrenheit, under the supervision of the Department of Health, and sealed with a label showing said process, as hereinafter provided.

NORTH CAROLINA.

Deaths for October.—During October there were reported to the State Board of Health 296 deaths, equivalent to an annual death rate of 15.2 per 1.000. the chief causes of death being consumption, 53; diarrheal diseases, 32; brain diseases, 29, and heart diseases, 23.

October Morbidity.—There was reported during October measles in 11 counties in the state. whooping cough in 24 counties, scarlet fever in 30 counties, diphtheria in 55 counties, typhoid fever in 57 counties, malarial fever in 15 counties, cerebrospinal meningitis in 6 counties, pneumonia in 26 counties and varicella in one county.

What Constitutes Immoral Conduct.—At the last session of the State Medical Society, resolutions were adopted urging the State Board of Medical Examiners to revoke the license of any physician found guilty of illegally prescribing alcoholic liquors. An added interest has recently been given to this power of the State Board by the law authorizing the board to revoke medical licenses for grossly immoral conduct. In a recent decision of the Supreme Court of the state, the conviction of a negro lawyer for the illegal sale of liquor, was held not to be sufficient ground to disbar him from practice of law in the state. and since this decision many physicians have raised the question as to what conduct is considered sufficiently immoral to justify the revocation of the license.

OHIO.

District Society Meeting.—At the fifth annual meeting of the Eighth District Medical Society, held in Athens, November 19. Dr. Neal T. McTeague, New Lexington, was elected district president; the various presidents of the component county medical societies were made vice-presidents. and Dr. William E. Wright, Newark, was re-elected secretary.

Geer Jury Disagrees.—In the case of Dr. Norman M. Geer, Cleveland, charged with performing an illegal operation, the jury disagreed, and was discharged November 25. The patient refused to testify, on the ground that she would thereby incriminate herself. This is said to be the sixth time in twelve years that this individual has been freed from different charges.

PENNSYLVANIA.

Bequest.—The will of the late Miss Darlington, of Downingtown, bequeaths $7,292 each to the Chester County Hospital and the Presbyterian Home for the Aged, Bala.

Typhoid Fever in Reading.—The epidemic of typhoid fever in Reading is now reported to be under control as only 16 new cases were reported on December 8. The total number of cases recorded to that date was 579. The source of the infection was found in the city's water supply.

New Hospital.—A fund for a new hospital has been started in Altoona and a charter applied for, the corporation is to have a capital stock of $60,000. Two excellent sites have been offered by Councils for the building. The project is supported by twenty-three physicans and the directors include many prominent business men of the city.

Philadelphia.

Gifts to Hospitals.—Donation day was observed Thanksgiving day at many of the hospitals. Through Dr. Charles S. Turnbull, senior medical officer at the German Hospital, that institution received $5,000 from Dr. and Mrs. William W. McClure, in memory of their son, the late Dr. Sorden McClure, to endow a bed for the members of the First Infantry, N. G. Pennsylvania. In addition to endowing a bed valued at $5,000, in memory of his father and mother, George W. Benner gave $8,000 in cash and goods valued at $700 to this hospital. St. Agnes' Hospital was the recipient of $2,000, the contributions ranging from 50 cents to $500.

Officers Elected.—At the regular meeting of the Society of Normal and Pathological Physiology, the following officers were elected: President, Dr. David H. Bergey; vice-president, Dr. H. C. Hickey, and Secretary and Treasurer, Dr. Harold B. Wood. At the last meeting of the Southeastern Medical Society and the Eastern Medical Society, those two bodies united and will hereafter be known as the Southwark Medical Society. The following officers have been elected: President, Dr. Max Staller; vice-president, Dr. Aaron Bray; secretary, Dr. M. B. Cooperman, and treasurer, Dr. Jacob J. Frankel.——The Kensington Branch of the Philadelphia County Medical Society has elected the following officers: Chairman, Dr. John J. Gilbride; clerk, Dr. William T. Dempsey.——The Committee on Public Policy and Legislation of the Philadelphia County Medical Society, as recently constituted, consists of the following men: Drs. James B. Walker, L. Webster Fox, William S. Higbee, James M. Anders and John Ruoff.

TEXAS.

Society Merger.—The Parker County and Palo Pinto County Medical Association recently merged.

Sanatorium Burned.—The Cates Sanatorium, Abilene, was destroyed by fire November 27, at a loss of $10,000, with no insurance.

Smallpox.—The State Department of Health has been advised of an epidemic of smallpox among negroes and Mexicans at Encinal, LaSalle County. About seventy-five cases of smallpox are reported in the vicinity of Oak Forest, mainly among negroes and Mexicans.

District Society Meetings.—At the annual meeting of the Eighth District Medical Society, held in Victoria, Dr Edward A. Malsch, Victoria, was elected president; Dr. A. L. Lincecum, Louise, vice-president, and Dr. Caspar W. Letzerich, Sublime, secretary-treasurer. Wharton was selected as the next place of meeting——At the annual meeting of the Fifth District Medical Society, held in San Antonio, November 20, Dr. George H. Moody, San Antonio, was elected president; Dr. Ewarts V. DePew, San Antonio, was re-elected secretary, and Dr. J. W. Woolsey, San Antonio, treasurer.

Personal.—Dr. Eben S. Cox, Galveston, health officer of Galveston County, while hunting, November 22, was wounded by the accidental discharge of the rifle. He is reported to be doing well.——Dr. Charles H. Phillips, Tyler, has abandoned the practice of medicine for the ministry.——Dr. Rufus B. West, Fort Worth, has been appointed physician of Tarrant County, and Dr. Henry B. Trigg has been elected County Farm physician.—Dr. Benjamin M. Worsham, superintendent of the State Insane Hospital, Austin, has resigned, to take effect January 1. He expects to engage in private practice, after making a tour of Europe.——Dr. Thomas C. McCurdy, house surgeon of the Texas Pacific Hospital, Marshall, has resigned and his place has been filled by Dr. Clarence R. Williams, who in turn has been succeeded by Dr. Charles M. Hall, Hico. ——Dr. Marcel W. Sherwood, Gainesville, has been made house surgeon at Temple for the Santa Fe Railway Employees' Hospital, vice Dr. Mark E. Lott, resigned to take position of chief surgeon of the Texas Central Railway, with headquarters at Walnut Springs.

VIRGINIA.

State Buys Sanitarium Site.—The State Board of Health has purchased from the proprietor of the Roanoke Red Sulphur Springs, that property, which will be operated as a State Sanitarium for Tuberculosis. The price paid by the state was $18,774.

Personal.—Dr. J. C. King has been made superintendent of the Southwestern State Hospital for the Insane, Marion, vice Dr. Albert S. Priddy, resigned.——Dr. Christopher F. Newbill, Norfolk, has given up practice on account of ill health.——Dr. Charles R. Grandy has been elected secretary-treasurer of the Antituberculosis League of Norfolk.

Society Meetings.—The Southside Virginia Medical Association, at its twenty-third annual session, held in Emporia, December 8, elected the following officers: President, Dr. Charles W. Astrop, Surry; vice-presidents, Drs. T. M. Raines, Wakefield; Edward M. Parker, Emporia, Walter L. Devaney, Dendron, and Richard H. Sims, Powellton; secretary, Dr. Emmett F. Reese, Courtland, and treasurer, Dr. Otto C. Wright, Jarrett. The next meeting of the association will be held in Petersburg.——The Church Hill Medical Society, Richmond, at its annual meeting, December 10, elected the following officers: President, Dr. Benjamin A. Hord; vice-presidents, Drs. Charles W. Massie and George W. Gay; secretary-treasurer, Dr. Ramon D. Garcin; and executive committee, Drs. Wyatt S. Beazley, William H. Parker and John S. Horsley.——At the annual meeting of the Richmond Academy of Medicine and Surgery, held December 8, the following officers were elected: President, Dr. McGuire Newton; vice-presidents, Drs. Marvin E. Nuckols, Manfred Call and Albert W. Freeman; secretary, Dr. Mark W. Peyser (re-elected); assistant secretary, Dr. W. Brownley Foster; librarian, Dr. G. Paul LaRoque, and treasurer, Dr. William A. Shepherd.

GENERAL NEWS AND COMMENT.

Southern Gynecologists Elect.—At the annual meeting of the Southern Surgical and Gynecological Association, held in St. Louis, December 15-17, the following officers were elected: Dr. Stuart McGuire, Richmond, Va., president; Drs. John Young Brown, St. Louis, and Robert S. Cathcart, Charleston, S. C., vice-presidents; and Dr. William S. Goldsmith, Atlanta, Ga., treasurer. Hot Springs, Va., was selected as the meeting place for 1909.

International Society for Esperantist Medical Students.—An error occurred in our note on this subject (THE JOURNAL, Nov. 21, 1908, p. 1791). The secretary is not *Dr. Robin*, but Mr. A. R. Badert, 35 Rue Michelet, Tours, France, to whom all communications should be addressed.

Ophthalmology Congress.—Dr. G. C. Savage, Nashville, Tenn., has been made secretary of the American committee of the Eleventh International Congress of Ophthalmology, which will meet in Naples, Italy, April 2 to 7, 1909. Any member of the profession desiring information concerning this congress and concerning the cost of the trip will receive the information from him on request.

Pediatric Society Election.—At the annual meeting of the New England Pediatric Society, held in Boston November 28, the following officers were elected: President, Dr. Charles W. Townsend, Boston; vice-president, Dr. Addison S. Thayer, Portland, Maine; secretary-treasurer, Dr. Fritz B. Talbot, Brookline, and councilors, Drs. John Lovett Morse, Boston, Charles P. Putnam, Boston, and Arthur H. Wentworth, Boston.

Seaboard Physicians Meet.—At the thirteenth annual session of the Seaboard Medical Association, whose membership is composed of physicians of eastern North Carolina and southeastern Virginia, held in Washington December 1 to 3, the following officers were elected: President, Dr. Southgate Leigh, Norfolk, Va.; vice-presidents, Drs. J. W. Hathaway, Wimfall, N. C., C. D. Dellam, Norfolk, Va., Benjamin F. Halsey, Roper, N. C., and Robert L. Payne, Jr., Norfolk, Va.; secretary, Dr. John R. Bagbey, Newport News, Va.; treasurer, Dr. Israel Brown, Norfolk, Va., and orator, W. Thomas Parrott, Kingston, N. C. It was voted to hold the session of 1909 in Norfolk.

FOREIGN.

French Medical College in Cochin China.—The medical school founded by the French at Hanoi is reported in a flourishing condition, with 90 pupils. Its five graduates last year are in active practice and five more graduate this year.

Historical Medical Exhibit in Spain.—A retrospective medical museum is being organized by the Madrid Medical Society, the *Colegio de Medicos,* and interesting medical treasures, forgotten in attics, are being rediscovered throughout the country. A good start with the museum has already been obtained by donations from Madrid physicians.

Educational Circulars for Protection Against Infectious Diseases.—The Italian government is issuing a series of circulars, written in popular style, for free distribution among the masses, to instruct them in the measures to protect the individual against infectious diseases. Thirteen have already been published, dealing each with a separate disease: Smallpox, scarlet fever, measles, typhoid, cholera, dysentery, miners' anemia, tuberculosis, malaria, diphtheria or trachoma.

Fourth Latin-American Medical Congress.—The official bulletin of the next Latin-American congress states that the meeting will convene at Rio de Janeiro in August, 1909. Nine sections have been organized and the work of the congress is well under way. The editor of the *Brazil-Medico,* Prof. A. de Azevedo Sodré, is the president of the committee on organization, and Prof. A. Peixoto, also on the editorial staff of the *Brazil Medico,* is the secretary general. An exhibition of hygiene is to be one of the features of the congress. Address, rua da Uruguayana 5, Rio de Janeiro, Brazil.

Yellow Fever Commission for the French Colonies in the Antilles.—The recent small epidemic of yellow fever at Saint-Nazaire on the French coast has impressed on the authorities the necessity for more effectual measures against yellow fever in the French colonies, whence the disease was imported. The task was entrusted to Drs. Simond and Marchoux, who spent some time in Brazil two or three years ago in study of tropical diseases. They left for Martinique November 11, fully equipped for the extermination of yellow fever and malaria mosquitoes in Martinique and Guadeloupe.

Occupational Affections.—The permanent international committee for the study and prevention of occupational diseases, of which Professor De Cristoforis of Milan is chairman, has published a circular with instructions for prevention of lead poisoning, and has distributed thousands of copies among the pupils of the technical schools and the workmen in industrial establishments in Italy. The committee has also succeeded in having a section for occupational affections included on the program of the approaching International Medical Congress at Budapest. Milan was the first city to establish a dispensary and clinic exclusively for professional or occupational affections. It owes its inception to and is in charge of De Cristoforis.

PARIS LETTER.

(From Our Regular Correspondent.)

PARIS, Dec. 12, 1908.

An Inquiry Into the Privat-Docent System.

Among the various projects for reform in medical education now being discussed (Paris Letter, THE JOURNAL, Oct. 19, 1908, li. 1023), is one for the suppression of the position of *professeur agrégé,* the lowest grade of the teaching body, which it is proposed to replace by the privat-docent system, in vogue in Germany and elsewhere. The partisans of the *statu quo* (Professor Bouchard, among others) maintain that Germany herself suffers from this institution and is seeking to be rid of it; but the results of an inquiry recently made in Germany in regard to the privat-docent system do not support Bouchard's views. Professor Bier of Berlin says that he has never heard that any one wished to abolish the privat-docent system, and that he is sure that such a project would arouse the hearty opposition of the professors. Bier himself believes that the privat-docents are indispensable to the students, and impart a large share of the instruction given. The great majority of the most celebrated German professors have emerged from the ranks of the privat-docents. Bier and other German professors do not believe that the professional or material interests of the practitioners are at all injured by the privat-docents. Dr. Cohn of Frankfort writes that, far from wishing to suppress the privat-docent system, Germany is proud of it, for to this institution the Germans owe their remarkable progress in many branches for which there are no professors at the universities. These young scientists have conquered for their specialties the right of existence.

Compulsory Physical Education.

The reduction of the term of military service in France to two years has created a demand for previous training of young men. Formerly, when they were kept in the army for seven, five or three years, military instruction was comparatively easy. To obtain the same result in two years, however, it is necessary that the recruits shall undergo preparatory training. Numerous societies (5,065 in all, with 869,000 members) have been formed for gymnastics, military instruction, drilling, athletic sports, etc., to prepare the recruits for their vocation. But the task of the physical education of young people ought to be more generally undertaken. A bill providing for the compulsory physical education of all pupils in public schools has accordingly just been submitted to the parliamentary committee on physical education.

The Hygiene of Lodging-Houses.

The prefect of police has just issued an ordinance regulating the sanitation of furnished lodgings. This prescribes the cubic air-space which each room offered for rent must contain per person, and enumerates the measures which the lodging-house keeper must take in respect to rendering the floors impermeable and covering and cleaning the walls. The rooms are to be suitably ventilated; when they contain more than four lodgers, they are to be provided with a flue or some other permanent means of aëration. In the rooms on the ground floor, where dampness might be felt, the lower portion of the walls is to be covered with an impermeable coating or with a wainscoting isolated from the wall at least up to five feet from the floor.

The ordinance forbids the renting for furnished lodgings of rooms which are not either lighted and aired directly or from a vestibule or corridor which itself receives the light and air directly from outdoors. Every room which contains more than two persons must be lighted directly. It is forbidden to rent cellars and basements for lodgings. In the case of epidemic or contagious maladies occurring in a lodging-house, a physician will be officially sent to ascertain the nature of the malady, and the lodging-house keeper will be held responsible for obedience to the directions for preventing the spread of the disease, such as isolation of the patients, disinfection of linen, etc.

BERLIN LETTER.

(From Our Regular Correspondent.)

BERLIN, Nov. 26, 1908.

Overproduction of Medical Literature.

The well-known tendency of the Germans to found associations finds an analogy in the passion for publishing periodicals, and this peculiarity has manifested itself to an actually alarming extent in the field of medicine. Already in 1903 there were about 240 German periodicals in medical literature, and since then dozens of new organs have been founded. It is indeed not too much to claim that Germany stands at the head of all civilized nations in the extent of its medical literary output, a fact that I do not wish to emphasize in a boasting spirit, for naturally the value of the contents does not correspond to the extent and number of the articles published each year. Only a certain fraction of this literature deserves in reality to have seen the light of the world. Although much has been written and is still being written against this practice, no improvement is either to be demonstrated or even hoped for.

Lately a new journal has been founded which opens up a very objectionable prospect for the extension of our literature. As if it were not enough that three or four journals exist for urology, which indeed constitutes a very recent special field (there is much room for discussion as to the propriety of separating it from surgery), there has now been introduced a journal devoted exclusively to gynecologic urology, the *Zeitschrift für gynäkologische Urologie,* on the specious ground that the other journals devoted to urology do not cover this special field. If this idea should happen to act fruitfully on publishers and on those physicians who feel a call to editorial work, there will soon be separate journals for surgery, internal medicine, nasal diseases, ear diseases, etc., in men, in women, and in children! It seems incredible that publishers can be found willing to invest their money in such undertakings in which success can scarcely be anticipated, even by the most determined optimist. But whether such an enterprise becomes a financial success or not, it will be kept up, even if at a sacrifice, and literature be injured by it. A review of what appears in German medical literature is no longer possible for any one; it is impossible to keep up fully with the literature even of one's own specialty And yet if in any work this or that previous publication fails to receive notice unedifying polemical discussions ensue which in their turn increase the ballast of medical literature

Lately it has become a favorite practice when an editor undertakes the foundation of a new journal for him to employ as a leading team to introduce his organ a group of more or less well known authors whose names he puts on the title page as the editorial staff or publishers the *Herausgeber* Mere vanity causes even scientists of wide reputation beyond the need of advertising themselves to give their consent to this measure and allow the use of their names as a sign board for new journals of this description In the rarest cases only do these 'publishers" who in the true sense of this term are responsible for the contents of their journal cast more than a glance at the various issues of the journal Thus it happens that they protect with their names a publication which is a disgrace to the literature A scandal which will perhaps finally open the eyes of some of these gentlemen appears to have developed in relation to one of these publications Two years ago there was founded in Berlin the *Zeitschrift fur neuere physikalische Medizin* (editor Dr Zikel) which according to the title page constitutes a professional organ for the practically important methods of the newer diagnosis and physical therapy As "publishers ' in addition to some unknown foreign physicians distinguished German scientists were introduced such as Czerny and Erb (of Heidelberg), von Leyden von Noorden v Strumpell etc For every reader of any observation there was something at least suspicious in the editorial and advertising columns of even the very first number of this journal From both parts one gets the impression that under the cloak of science commercial aims were being pursued It was not quite clear in whose favor this course was followed as the remedies recommended were changed in the course of time Lately the zeal of the editor seems to have turned especially to the promotion of an article known as Kathreiner's Malt Coffee, and at the same time chicory as a substitute for coffee was denounced (evidently from the same point of view) A few weeks ago a pamphlet appeared written by the head of a Bremen coffee firm which characterized the *Zeitschrift fur neuere physikalische Therapie* as a business scheme of the Kathreiner Malt Coffee factory According to this pamphlet the edition of the journal amounts to 4 000 copies of which however in reality only 100 to 150 are sent to actual subscribers while all the other copies are distributed gratis to physicians advertising agencies etc The articles against coffee are said to have been secured by the business manager of the Kathreiner Malt Coffee factory, Mr Aust, a leading business man in Munich and all had to be submitted to him for approval before they were printed

I omit the particularly severe accusations which were made against the editor Dr Zikel and confine myself merely to the concluding summary of the author of the pamphlet In it he accused Dr Zikel of scientific imposture, he claimed that this fraud was undertaken in the interests of Kathreiner's Malt Coffee factory and he claimed that Dr Zikel himself was one of the most venal members of the medical profession Dr Zikel has now under the pressure of this accusation felt himself compelled to have proceedings instituted against himself before the Berlin Court of Honor in order to exculpate himself from the accusation The outcome of this proceeding is naturally awaited with great interest Already the pamphlet has had the result that some of the professors listed as publishers" have explained that their names were used without their knowledge and without their consent Surely this fact permits an unfavorable conclusion regarding the other editorial acts of Dr Zikel

The Appropriations for Medical Purposes for 1909

The budget just sent to the Reichstag by the imperial government contains the following apportionments for medical purposes For the fight against typhoid as in former years 200 000 marks ($48 000) For investigation of syphilis 30 000 marks ($7 200) For the campaign against infant mortality again 40 000 marks ($9 600) For the fight against tuberculosis again 120 000 marks ($28 800) For a statistical investigation of industrial accidents which was taken up in 1907 250 000 marks ($60 000) were set apart as the last installment A convalescent home is to be erected at Bad Nauheim for which the imperial government appropriates 13 000 marks ($3 120) The burden on the empire on account of the invalid insurance law amounts for the year 1909 to about 51 500 000 marks (nearly $13 000 000)

The Nobel Prize for Medical Research

This year's Nobel prize for medicine (about 150,000 marks —$36 000) is to be divided between Metchnikoff of Paris and Ehrlich of Frankfurt a M It is perhaps a question as to which of the two scientists is the more deserving At any rate it may be claimed that scientific and practical medicine has Ehrlich to thank for more progress than is due to Metchnikoff Ehrlich is now in the full vigor of his activity and lately delivered before the German Chemical Society here a very inspiring address on the present status of chemotherapy, which permits very remarkable glimpses into the further development of this branch of science Ehrlich's researches in regard to diphtheria antitoxin, which first made possible the practical application of v Behring's discovery and his investigation of cancer, etc, are achievements of the first rank Metchnikoff's activity in scientific investigation practically ceased some years ago, his more recent publications on natural death in old age and on a curative serum for old age show that we can hardly expect any further notable achievements from him

Care of Parturients

The trades committee of the Reichstag is considering a bill which requires that parturient women shall not be employed for eight weeks before and after delivery The resumption of work shall be conditioned on evidence that at least six weeks have passed since parturition Childbirth is to be classed with sickness so far as the right to sick benefit is concerned At present it is left to the discretion of the sick benefit societies the *Krankenkassen* whether they shall allow the parturient pecuniary aid or not

The Campaign Against Tuberculosis

In connection with the celebration of the hundredth anniversary of its incorporation as a Prussian city the municipal authorities of Schoneberg (near Berlin) have devoted 250,000 marks to combating tuberculosis With this sum a sanatorium for lung affections is to be built and a convalescent home for weakly children is to be founded on the island of Fohr, in the North Sea

VIENNA LETTER.

(From Our Regular Correspondent)

VIENNA, Dec 12, 1908

American Students in Vienna.

The American colony in the Vienna hospitals is not as large now as it was a couple of years ago Still, there are many physicians from the United States among the students, and it is notable that there are more earnest workers The men who used to take only a class or two and who then returned as full fledged specialists have disappeared almost completely for some unknown reason—perhaps the hard times of last year or perhaps 'natural selection" The classes comprise the whole scope of medicine and surgery, otology and laryngo rhinology are prominent subjects

Protection of Children from "Sweating."

In a recent bill the government proposes modern regulation of home work and especially child labor Thus, no child under 12 may be employed or hired out, as is the custom here for indoor work involving undue strain on the eye or the whole body or special attention to a machine No child under 14 may be kept working indoors longer than four hours For outdoor occupation, children must be at least 10 years old, and up to the age of 14 must not be employed in carrying heavy loads A series of inspections of rural factories, stone quarries brick factories and the like have given ample proof, not only of the fact that the health of children employed there suffers, but that the race tends to degenerate if children of early age are exposed to undue strain for a long period, and that the morality and temperate habits as well as the physical constitution, of children subjected to such strain are apt to suffer seriously The bill proposes the creation of special inspectors perhaps female for industrial concerns in the rural districts In cities strict compliance with the law is ensured by the power given to school authorities to report all cases in which violation is suspected Elementary education is compulsory so neglect is easily observed At present about 30 per cent of children in the country must help their parents in their work but such labor will not come within the scope of the law if it can be shown that the children are not overtaxed To badly developed children between the ages of 14 and 16 the same rules will apply as to younger ones

Pharmacology

THE ALPHA MEDICAL INSTITUTE.

Another Fraudulent Concern Closes Its Doors.

The Alpha Medical Institute of Cincinnati, a "consumption cure" fake has gone out of business. This concern, which was one of the Great American Frauds exposed by Samuel Hopkins Adams, was founded by the late Dr. Thomas W. Graydon, who "amassed a fortune from his understanding of the financial possibilities of tuberculosis." In its advertising pamphlet the "institute" is pictured as a large and commodious building bearing its sign; no such building ever existed outside of the imagination of the advertising agent. The "treatment" itself was "a combination of worthless inhalation with worse than worthless medicines." In discussing this concern and detailing the result of his personal interview with its manager, Mr. Adams says of the latter: "His one argument was that he could produce testimonials, and his one plea, that the institute ought not to be 'pounded' as it was going out of business in a few months, anyway. This means that the field is exhausted; that, as invariably will happen, the accumulated force of experience, proving the Alpha Medical Institute to be a fraud, has finally overcome the counter-force of its advertising. Probably its proprietors (I understand that Dr. Graydon's sons have got rid of the business as a baneful influence on their social aspirations) will presently start up under some other name."

While the Alpha Medical Institute was doubtless in a sickly condition, it was the United States government which gave it the *coup de grâce*. After considerable evidence had been collected, the Postoffice Department cited the company to show cause why a fraud order should not be issued. Instead, a representative of the company pleaded guilty—and that is Omega of Alpha.

Perspiro and Its Genesis.

Detroit, Oct. 18, 1908.

To the Editor:—A medical friend wrote a prescription for one of his patients for excessive sweating of the feet, the formula being that of the well-known Thiersche's powder:

℞.	gm.		
Salicylic acid	1	or	gr. xv
Boric acid	*10*		*ʒiiss*

The patient discovered he had a "good thing" and has placed it on the market under the euphonious name of "Perspiro." He sells with the powder twelve 1-grain tablets of permanganate of potash with instructions to soak the feet each night in hot water in which is dissolved one of the permanganate tablets. The salicylic acid in the powder attacks the socks so that they are soon full of holes.

E. T. Milligan, M.D.

A "Shot Gun."

The following prescription was given by a physician to a patient during the last three months:

℞. Merck's Colchicin
" Strychn. Phos., āā ....grs. ii
" Sod. iodid
" " salicyl., āā ....ʒx
Tr. Belladonnæ
" Bryonia alb., āā ....ʒii
" Capsicum ....ʒi
" Arnica mont
" Pulsatilla
" Rhus tox. āā ....ʒv
" Phytolocca ....ʒx
" Cimicif. Rac.
" Colchicum. āā ....ʒxv
Reed and Carnick's Elix. Peptenzyme........ʒlx

M. S. Take sixty (60) minims (drops) in a glassful of water, an hour after each meal. Take every 2 hours if very severe.

The Abuse of the Tablet.

The convenience of the tablet form of medication has doubtless developed in the medicine-taking public a dangerous contempt for potent drugs that has been bred of familiarity. This was recently exemplified by the case reported in our British contemporaries of a woman who took thirteen aspirin tablets between 3 p. m. one day and 10 a. m. the next. She died of heart failure and, in accordance with the medical testimony, a verdict was returned of death accelerated by an overdose of aspirin.

The very advantages that a tablet has in case of administration, convenience and portability, are in themselves elements of danger when drugs in this form are indiscriminately used by the public.

Correspondence

The Burial Place of Dr. John H. Rauch.

Lebanon, Pa., Dec. 13, 1908.

To the Editor:—In several recent numbers of The Journal I find tributes to the memory of Dr. John H. Rauch. George Homan, M.D., Secretary of the State Board of Health of Missouri, states that he does not know where the body of Dr. Rauch is buried or whether the spot is marked by any memorial adequately showing the vastness and value of his work.

Dr. John H. Rauch reached Lebanon, Pa. (his birthplace and the home of his relatives) from Chicago, wearied, worried, despondent and in ill health, in the autumn of 1893. Nevertheless, his interest in his life-work forced him to continue writing to The Journal and collecting data on the topics in which he was interested.

His family life with his relatives here was very pleasant and seemed to cheer him, but on the morning of March 24, 1894, I was hurriedly called to his brother's home, where he was staying, to find him dead in his bed; he had retired, complaining of a pain on his chest, but during the night had not called for any attention by the family; he had apparently died several hours before daybreak. His body rests in our local cemetery.

As an old friend, he spent much of his time in my company, and I know he felt keenly his retirement from active participation in the work to which he had devoted himself and the ingratitude manifested.

The effort of the medical profession, and especially of the State of Illinois, to honor his work and his memory, comes late, but will, I hope, result in some suitable action. His interest in the public park system of Chicago, which he originated as a health measure as well as a matter of civic pride, might earn for him a recognition in naming one of the parks for him, or in erecting in one of them a monument reciting his activities in federal, state and municipal work.

W. M. Guilford.

Legislation on Animal Experimentation in New York.

New York, December, 1908.

To the Editor:—Last winter two decided efforts were made before the legislature of this state by two separate organizations to secure the enactment of laws seriously restricting animal experimentation as a means of established scientific medical progress. These efforts will be repeated during the coming session of the legislature. On Nov. 11, 1908, a concert was given in this city by the New York Antivivisection Society for the purpose of advancing their aims in this respect. A pamphlet is now being circulated among physicians and others in various parts of the state by the Society for the Prevention of Abuse in Animal Experimentation, calling attention to the assumed horrors of vivisection and urging support in the effort which the society will make at the coming session of the legislature to secure restrictive legislation. This pamphlet, a typical piece of antivivisection literature, is evidently the work of one whose eyes are shut to the real state of facts, for the allegations made therein are unjustified and unsupported by proof. They are based largely on obsolete European methods. No reliable evidence that needless suffering is inflicted in animal experimentation in laboratories or elsewhere has been brought to light by the opponents of vivisection Eminent legal authorities assure us that the law as it exists to day in the State of New York is sufficient to punish all, if there be such, who are guilty of cruelties in animal experimentation.

If restrictive laws pertaining to this subject are introduced into the legislature this winter, the Medical Society of the State of New York will oppose them. In the meantime we urge the public to refrain from accepting as true such a misleading picture as is presented in the pamphlet above referred to The Medical Society of the State of New York is prepared to furnish literature expressing the truth regarding animal experimentation and also to furnish speakers for clubs and societies that are interested in this subject.

Frank Van Fleet, M D,
Chairman, Committee on Legislation, Medical Society of the State of New York

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U S Army, week ending Dec 19, 1908

Greenleaf, H S, capt, granted leave of absence for 30 days

Maus L M, col, relieved from duty as chief surgeon, Department of Luzon, and ordered to report as chief surgeon, Philippine Division, relieved from duty in Philippines Division, April 15, 1909, and ordered to San Francisco, for orders

Crampton, L W, col, relieved from duty in charge of the medical supply depot, St Louis, in time to sail March 5, 1909, from San Francisco, for duty in the Philippines Division

Reed, H A, lieut, ordered to Ft Bayard, N M, for treatment at the Army General Hospital

Hoff, J V R, col, granted leave of absence for two months, with permission to return to the U. S via Europe

Lewis, W F, major, granted leave of absence for 15 days

Torney, G H, col, granted leave of absence for 15 days

Shepheid, J M, M R C, died Dec 11, 1908 at Salt Lake City, of general peritonitis, complicated with appendicitis

Lugo-Vina, Jose, cont surg, contract annulled Nov 23, 1908

Murray, Wilson, and Dougherty, J C, cont surgs, contracts annulled to accept active duty in the M R C

Dosher, J A, cont surg, contract annulled Dec 3, 1908, services being no longer required

Stallman, G E, dent surg, left Fort Sill Okla, for duty at Fort Sam Houston, Texas

Whinnery, J C, dent surg, left Ft Ward, Wash, for duty at Fort George Wright Wash

Tignor, E P, dent surg, left Ft Howard, Md, and arrived at Ft McHenry, Md, for duty.

Navy Changes.

Changes in Medical Corps, U S Navy, for week ending Dec. 19, 1908.

Riggs, R E, P A surgeon, granted leave under exceptional circumstances with permission to visit the United States to take effect about December 19 and to terminate on departure from Newport News, Va, of the transport to sail for Havana, Cuba, about December 31

Robnett, A H, asst surgeon Camp Columbia, Cuba will proceed to Santo Domingo, Province of Santa Clara, Cuba and report December 17 for temporary duty during absence on leave of P A Surgeon R E Riggs

Alderman, C G, asst surgeon, granted sick leave for three months when discharged from treatment at the naval hospital, Las Animas Colo

Brown, E W, asst surgeon, unexpired portion of sick leave revoked, ordered to course of instruction at the Naval Medical School, Washington D C

Rothganger, G, surgeon, transferred to the retired list from Dec 10 1908 in accordance with the provisions of section 1453 of the Revised Statutes

Brooks, F H, asst surgeon, detached from the naval recruiting station, Cleveland Ohio, and ordered to the *Franklin*

Thomas, G E, acting asst surgeon, ordered to the naval hospital, navy yard Boston for duty

Thompson, F. W, acting asst surgeon, appointed acting assistant surgeon from Dec 12, 1908

Randall, J A, P A surgeon, detached from the *Rainbow* and ordered to duty at the naval hospital, Canacao P I

Balch, A W, P A surgeon, detached from the naval hospital, Cavite, P. I, and ordered home via the *Concord* and *Supply*

Lee, A E, asst surgeon, detached from the *Concord* and ordered to the *Rainbow*

Downey, J O, asst surgeon detached from the *Charleston* and ordered to duty at the naval hospital, Canacao, P I

Higgins M E, asst surgeon, detached from the naval hospital, Canacao, P I, and ordered to the *Charleston*

Butts, H asst surgeon detached from the naval hospital, Canacao P I and ordered to the naval station, Cavite, P I

Alexander, C E, pharmacist, detached from the *Relief* and ordered home via the *Concord* and *Supply*

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and other officers of the Public Health and Marine Hospital Service for the seven days ended Dec 16, 1908

Lavinder, C H P. A surgeon on arrival of Assistant Surgeon Lasher Hart, relieved from duty at Stapleton, N Y, and directed to report at the Hygienic Laboratory for temporary duty

Ramus Carl, P A surgeon, granted 2 days' leave of absence from Dec 7, 1908, on account of sickness

Earle, B H P A surgeon granted 12 days' leave of absence from Dec 24 1908

Burkhalter, J. T, P A surgeon, granted 1 month's leave of absence from Dec 19, 1908

Foster A D, P A surgeon, relieved from temporary duty at Angel Island, Cal, on or about Jan 5, 1909, and directed to proceed via Manila P I, to Amboy, China, for duty in the office of the United States consul

Olesen, Robert, asst-surgeon, relieved from temporary duty at San Francisco on or about Jan 5 1909, and directed to report to the chief quarantine officer of the Philippine Islands

Hart, Lasher asst surgeon, relieved from temporary duty at Hygienic Laboratory, and directed to rejoin station at Stapleton, N. Y

Hunt, Reid, Chief Division of Pharmacology, Hygienic Laboratory, granted 9 days' leave of absence from Dec 11, 1908

Cleaves, F H, acting asst surgeon, granted 10 days' leave of absence from Dec 19, 1908

Hume, Lea, acting asst surgeon, granted 10 days' leave of absence from Dec 15 1908

Parker, T F, acting asst surgeon, granted 5 days' leave of absence from Dec 27, 1908

BOARD CONVENED

Board of medical officers convened to meet at the bureau on Jan 11, 1909, for the examination of assistant surgeons for promotion to the grade of passed assistant surgeon, and for the examination of candidates for admission to the service as assistant surgeon Detail for the board Surgeon G W Stoner, chairman Passed Assistant Surgeon Joseph Goldberger and Passed Assistant Surgeon B S Warren, recorder

Health Reports.

The following cases of smallpox yellow fever, cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service, during the week ended Jan 18, 1908

SMALLPOX—UNITED STATES

California San Francisco, Nov 22 29, 3 cases.
Illinois Danville, Nov 30 Dec 6, 1 case
Indiana Lafayette Dec 1 7, 4 cases
Kansas Kansas City, Nov 28 Dec 5, 1 case; Topeka, 5 cases.
Louisana New Orleans, Nov 28 Dec 5, 1 case, imported
Michigan Grand Rapids, Nov 14 21, 1 case
Minnesota Stillwater, Nov 1 30, 1 case
Montana Butte Nov 24 Dec 1, 3 cases
Ohio Cincinnati, Nov 27 Dec 11, 15 cases
Tennessee Knoxville, Nov 28 Dec 5, 1 case
Wisconsin LaCrosse, Nov 28 Dec 5, 4 cases, Manitowoc, Nov. 21 Dec 5, 21 cases

SMALLPOX—FOREIGN

China Amoy (Kulangsu), Oct 10 Nov 8, 2 deaths
France Toulon Oct 1 31, 1 case
Italy General, Nov 15 22, 25 cases; Naples, 15 cases

YELLOW FEVER

Mexico Mexcanu, Nov 21 28, 1 case; Merida, 3 cases, 1 death; Vera Cruz, 1 case

CHOLERA.

Russia General, to Nov 14, 27,160 cases, 12,802 deaths

PLAGUE

Azores Terceira, Oct 1 31, 53 cases, 33 deaths
India General, Oct 17 31, 4,186 cases, 3 841 deaths
Peru General Oct. 27 Nov 4, 30 cases, 21 deaths, Callao, Nov 14, 2 cases, Lima, 2 cases

ALLEGED CONSUMPTION CURES

Castroville, Texas, Dec 9, 1908

To the Editor:—Referring to the exposures of "Consumption Cures," I would like to call attention to a statement in "Ancient Pharmacy and Medicine," Peters, translated by Dr Netter, in which it is stated that the first "patent medicine' was a "consumption cure' called "Tuscarora Rice" sold by a Mrs Masters in 1711 in the United States It would seem that the cure of consumption has always been a fertile field for robbing the unfortunate by new *discoveries*"

J I F

DEFINITION OF INCIDENCE

To the Editor —Please define the word "incidence," as used under "Cholelithiasis. Etiology' in the Program for the Second Six Months of Postgraduate Study

M C

Answer —"Incidence' is defined by the Century Dictionary as 'the manner of falling, direction of the line of *fall*" Under incidence of a disease is usually discussed its frequency with relation to age sex, race etc; in other words, it means the direction which the disease may be expected to take, viewing as the objective point those persons who for any reason may be expected to be subject to it.

CAUSE OF EROTIC ABERRATIONS IN THE AGED.

Columbus, Ohio Dec. 12, 1908.

To the Editor:—I am interested in the editorial on the above subject in The Journal, December 12, and the suggestion contained therein *in regard to the possibility of these aberrations* being due to abnormality in involution of sexual organs. It has occurred to me that possibly the cortical portion of the adrenal might have something to do with these conditions in the aged. The cortical portion of this ductless gland has been observed to be hypertrophied in cases of extraordinary sexual development, and to be atrophied when sexual power was low. Often in animals, such as rabbits, used for experimental purposes, the cortex of the adrenal atrophies during pregnancy; and in other animals changes often occur during the mating period. Have we any definite information in regard to the adrenals in these cases of belated sexual overactivity in the aged? E. F. McCampbell.

TECHNIC OF HASTING'S BLOOD STAIN.

Hardin, Mont., Dec. 5, 1908.

To the Editor:—Please give the technic of Hasting's blood stain and references. W. C. Richards.

Answer.—Hasting's stain is a modification of Nocht's stain and consists of a powder, which is dissolved in methyl alcohol. To prepare the powder three solutions are required: A, 1 per cent. aqueous solution of yellow eosin (Grübler); B, freshly prepared polychrome methylene blue solution; and C, 1 per cent. aqueous solution of Ehrlich's rectified methylene blue (Grübler). Solution B is freshly prepared by adding to a warm 1 per cent. solution of dry powdered sodium carbonate 1 per cent. of methylene blue powder. The mixture is heated on a water bath for fifteen minutes; 30 c.c. of water are added for each 100 c.c. of original fluid to replace loss by evaporation. This is heated a second time on the water bath for fifteen minutes; 200 c.c. of this mixture should be prepared for one batch of stain. This warm alkaline methylene blue solution is poured off from the gummy residue and partly neutralized with 5 to 6 c.c. of 12.5 per cent. acetic acid and mixed with solutions A and C as follows: Distilled water 1000 parts, A 100 parts, B 200 parts, C 70 parts. After the addition of C a greenish metallic scum appears on the surface and a fine black precipitate is thrown down. This precipitate may not appear until 80 c.c. of solution C have been added, but the addition of C should be continued until the precipitate is thrown down. The mixture should now be filtered and the residue on the filter should be dried in the air or in a hot-air chamber at a temperature not above 60 C. The dried residue is scraped from the filter, powdered in a mortar and dissolved in pure methyl alcohol; 7/10 to 1 gm. of the powder is usually obtained; 0.25 to 0.3 gm. will saturate 100 c.c. of pure methyl alcohol. In mixing in the mortar considerable pressure should be used to break up the powder. As methyl alcohol is sometimes acid it should be neutralized, if necessary, with sodium carbonate. The solution, when of proper strength, has a purple plum color and after being shaken leaves the sides of the bottle quite clear above the surface of the stain. The stain can be applied to dry films without previous fixation by simply flowing the liquid over the film, taking care to wipe off with the finger any of the stain which collects on the *side of the cover-glass not occupied* by the preparation.

For further directions see the original articles: Nocht: Centralbl. f Bacteriol., 1899, xxvi, 17. Hastings, F. W.: Johns Hopkins Hosp. Bull., April, 1904; Jour. Exper. Med., June, 1905.

Medical Education and State Boards of Registration

COMING EXAMINATIONS.

Arizona: Phoenix, Jan. 4-5. Sec., Dr. Ancil Martin.
Arkansas: Little Rock, Jan. 12. Secretaries: Regular, Dr. F. T. Murphy, Brinkley; Homeopathic, Dr. P. C. Williams, Texarkana: Eclectic, Dr. A. J Widener, Little Rock.
Colorado: Denver, Jan. 5. Sec., Dr. S. D. VanMeter, 1723 Tremont St.
District of Columbia: Washington, Jan. 12. Sec., Dr. George C. Ober, 210 B. St., S. E.
Illinois: Coliseum Annex, Chicago, Jan. 18-20. Sec., Dr. J. A. Egan, Springfield.
Minnesota: Old Capitol, St. Paul, Jan. 5. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg.
New Hampshire: Concord, Dec. 29-30. Regent, Mr. H. C. Morrison.

Washington: Spokane, Jan. 5-7. Sec., Dr. Kenneth Turner, Walker Bldg., Seattle.
Wisconsin: Milwaukee, Jan. 12-14. Sec., Dr. J. V. Stevens, Jefferson.

Medical Education and Nostrums.

The following is the first of a series of letters issued jointly by the Council on Medical Education and the Committee on Medical Teaching of the Council on Pharmacy and Chemistry:

To Medical Teachers:—This letter invites you to cooperate with the Council on Medical Education and with the Council on Pharmacy and Chemistry of the American Medical Association, in the movement to secure better conditions in Materia Medica and Therapeutics.

The progress of all branches of medical science is more or less directly retarded by certain abuses which have crept into to subjects of materia medica and therapeutics. Even the public is rapidly coming to realize our shortcomings in this respect, and the reputation of our profession must inevitably suffer if these branches are not placed on a sounder basis.

The responsibility for this condition can not be laid altogether at the door of the teaching departments which are directly involved. The roots of these abuses are much deeper and more extensive. The entire medical profession must share in the responsibility as well as in the results. Similarly, the reform of these conditions can only be accomplished by the cooperation of the entire medical profession. The responsibility for starting these reforms, however, lies *with the medical educators. Their example, their general influence*, as well as their direct teaching, must give the impetus if this movement for scientific therapeutics is to be successful. The Council on Medical Education has, therefore, undertaken to enlist your personal cooperation. The committee of the Council on Pharmacy and Chemistry will endeavor to keep you informed of its work and aims, and hopes to exchange with you suggestions as to the best methods of making this information effective.

Will you assist in this movement to purify our profession from the blight of the nostrum and similar evils? A thoughtful consideration of the problems, a word now and then, your example, and the full weight of your influence—your active support along these lines need not take up much of your time, but will help to accomplish vast results.

We shall address you further on this subject, and we trust that you will decide to assist in the work.

Marriages

Paul B. Cassidy, M.D., to Miss Frances Joy, both of Philadelphia, November 28.

Eugene H. Pitts, M.D., to Miss Maude Blue, both of Sacramento, Cal., December 9.

Homer Erastus Smith, M.D., to Miss Belle Goodrich, both of Norwich, N. Y., November 30.

Charles Henry Ewing, M.D., to Miss Florence Held, both of Roxborough, Pa., December 16.

J. Paul Keith, M.D., to Miss Myrtle Mae McCool, both of Hopkinsville, Ky., December 9.

Samuel D. Donovan, M.D., Dewey, Ill., to Miss Pearl Hoffman of Lovington, Ill., December 5.

Robert M. Gubbins, M.D., Ceresco, Mich., to Miss Dora Lutz of Marshall, Mich., December 9.

J. Homer Buckley, M.D., Fort Smith, Ark., to Miss London of New York City, December 12.

George William Beach, M.D., Binghamton, N. Y., to Miss Bertha Barnet of Chicago, December 3.

Roy White McClintock, M.D., to Miss Mattie Anna Weber, both of Chicago, November 14.

George Silas Duntley, M.D., to Miss Nola Blanche Seibert, both of Bushnell, Ill., December 2.

Walter Forman Wickes, M.D., to Mrs. Catherine Young Hobart, both of Chicago, December 16.

Margaret C. Woods, M.D., and James R. Stivers, both of Paris, Ky., at Lexington, Ky., recently.

Irvin M. Wertz, M.D., Hagerstown, Md., to Miss Jane Price Gaines, at Baltimore, December 10.

Archibald Olpp, M.D., Jersey City Heights, N. J., to Miss Beatrice Seiple of Philadelphia, November 26.

Frank Staples Bachelder, M.D., to Bertha May Louise Lypps, M.D., both of Pontiac, Mich., December 10.

Max Meitzner, M.D., Philadelphia, to Miss Bertha Eisele of Riverton, N. J., in Jersey City, N. J., December 2.

Edwin B. Miller, M.D., Altoona, Pa., to Miss Mary Weaver of Paradise, Pa., in Philadelphia, November 25.

Lawrence Orr McCalla, M.D., Eatonton, Ga., to Mrs. Bessie Jones Allen of Starr, near Anderson, S. C., December 2.

C. H. Showalter, M.D., Philadelphia, to Miss Lillian Alberta Ingram of Hagerstown, Md., at Camden, N. J., July 4.

Kennie M. Dwight, M.D., Muskogee, Okla., to Miss Florence E. Pierce of Hamilton, Mo., in Kansas City, December 5.

Thomas H. Higgins, M.D., Elizabeth, N. J., to Miss Helen C. Hoagland of Newark, N. J., in Asbury Park, N. J., November 10.

Deaths

John Elliott Russell, M.D. Starling Medical College, Columbus, Ohio, 1882; a member of the American Medical Association; and president of the Knox County Medical Society; for many years a member of the Knox County board of pension examiners; sometime trustee of the Massillon State Hospital and of the new State Hospital for the Criminal Insane now under construction at Lima; local surgeon for the Baltimore and Ohio, and Cleveland, Akron and Columbus railroads at Mt. Vernon; and in 1907 president of the Baltimore and Ohio Railway Surgeons' Association; a member of the National Association of Railway Surgeons; and one of the founders of the Ohio Society for the Prevention of Tuberculosis; died in the Millersburg (Ohio) Hospital, from nephritis, December 8, aged 48.

James Buckner Luckie, M.D. Pennsylvania Medical College, Philadelphia, 1855; a member and once a member of the council of the Medical Society of the State of Alabama; some-time president and censor of the Jefferson County Medical Society; assistant surgeon, medical purveyor, inspector of hospitals, and brigade surgeon in the Confederate service during the Civil War; senator from the twelfth Alabama district in 1880; a councilman and once chief of the fire department of Birmingham, Ala.; died at his home in Birmingham, December 12, from senile debility, aged 75.

William Mackie, M.B., C.M. University of Aberdeen, Scotland, 1879, M.D., 1881; a member of the American and British medical associations; surgeon to the Milwaukee Hospital and the Chicago, Milwaukee and St. Paul Railway; one of the best known surgeons of Milwaukee; once president of the Wisconsin State Medical Society and the Brainard District and Milwaukee medical societies; died suddenly at the home of his son in Milwaukee, December 9, from cerebral hemorrhage, aged 53.

John Lambert Nicholson, M.D. Tulane University, New Orleans, 1898; Harvard Medical School, Boston, 1900; of Nogales, Ariz.; a member of the Arizona Medical Association; from 1900 to 1903 Acting Assistant Surgeon U. S. Army in the Philippine Islands; inspector general of hospitals of the C. R. Y. and P. Railroad; died in the Sisters' Hospital, Tucson, Ariz., July 3, from multiple abscess of the liver, aged 43.

Edward M. Tucker, M.D. Medical School of Maine, Brunswick, 1872; a member of the New Hampshire Medical Society; and a well-known practitioner of Grafton County, N. H.; a veteran of the Civil War, and afterward hospital steward in the Army; for a number of years a member of the local school board, board of health and a justice of the peace of Canaan, N. H.; died at his home in Derry, December 8, aged 68.

Bryan Watkins Whitfield, M.D. University of Pennsylvania, Philadelphia, 1853; of Nauvoo, Ala.; for many years a member of the American Medical Association; sometime historian and councilor of the Medical Association of the State of Alabama; physician and surgeon to the Black Creek Coke Company; died at the home of his daughter in Demopolis, Ala., December 15, aged 80.

Jacob Warren Roop, M.D. University of Pennsylvania, Philadelphia, 1868; a member of the Medical Society of the State of Pennsylvania; president of Dauphin County Medical Society in 1898; for many years director, treasurer and president of the school board of Harrisburg; died at his home in that city, December 8, after a surgical operation, aged 65.

Edgar A. Stewart, M.D. Medical College of Ohio, Cincinnati, 1897; a member of the Ohio State Medical Association and a charter member of the Dayton Academy of Medicine; for two years city physician of Dayton; and for eight years thereafter assistant to the health department; died at his home in Dayton, December 10, from pneumonia, aged 41.

Frank Russell Baker, M.D. College of Physicians and Surgeons, New York City, 1889; a member of the Medical Society of the State of New York and a specialist on diseases of the nose and throat; fell from the window of his home in Williamsburg, December 11, while removing a screen, and was instantly killed, aged 39.

Mosley J. Toney, M.D. Maryland Medical College, Baltimore, 1905; a member of the American Medical Association; formerly of Northfork, W. Va., but later a resident of Aguilar, Colo.; died in the Glockner Sanitarium, Colorado Springs, December 10, from pulmonary hemorrhage, aged 31.

Gillis Stark, M.D. Dartmouth Medical School, Hanover, N. H., 1889; a member of the New Hampshire Medical Society; for two years a member of the board of mayor and aldermen of Manchester, N. H.; died suddenly at his home from cerebral hemorrhage, December 13, aged 43.

Edwin T. Bidwell, M.D. Yale Medical School, New Haven, Conn., 1847; a member of the Connecticut State Medical Society; and for nearly fifty years a practitioner of Deep River, Conn.; died at his home in that place, December 13, from senile debility, aged 87.

William Martin Ogden, M.D. Harvard Medical School, Boston, 1866; once vice-president of the Boston Microscopical Society and professor of general and dental surgery in the Boston Dental College; died at his home in Pasadena, Cal., December 3, aged 67.

Walter George Wilkins, M.D. London; in 1879 assistant superintendent of the New York Hospital; and in 1882 and 1883 superintendent of the Roosevelt Hospital; died at his home in Hammonton, N. J., June 29, from organic heart disease, aged 59.

Robert Wilson Robinson, M.D. Medical College of Virginia, Richmond, 1891; health officer of Danville, Va., for eight years; and visiting surgeon to the Danville General Hospital; died at his home in that city, from heart disease, December 12, aged 39.

Abraham Morrell Cory, M.D. Philadelphia College of Medicine and Surgery, 1857; a surgeon during the Civil War; inventor of the universal solar clock; a genealogist of renown; died at his home in New Providence, N. J., December 16, aged 80.

Levi F. Rinehart (license, Ohio, 1896); a member of the Ohio State Medical Association; for thirty years a practitioner of Perry County, Ohio; died suddenly at his home in New Lexington, December 13, from heart disease, aged 68.

John Harvey Winn, M.D. Starling Medical College, Columbus, 1874; a member of the Ohio State Medical Association; coroner-elect of Gallia County, Ohio; died at his home in Rio Grande, December 5, from malignant disease, aged 59.

Stevenson A. Caldwell, M.D. Northwestern Medical College, St. Joseph, Mo., 1886; of Little Sioux, Iowa; a member of the American Medical Association; died suddenly from cerebral hemorrhage, while making a professional call, December 14.

Tobias Berger, M.D. University of Vienna, Austria, 1890; president of the Eastern Medical Society and a member of the German Medical Society of New York; died at his home in New York City, December 13, from heart disease, aged 44.

Joseph Fleming Perkins, M.D. University of Maryland, Baltimore, 1875; Bellevue Hospital Medical College, New York City, 1879; a specialist in diseases of the throat; died at his home in New York City, December 8, aged 57.

Stewart Robertson, M.D. New York University, New York City, 1884; of Allegheny, Pa.; a member of the American Medical Association; died in the Presbyterian Hospital, Pittsburg, December 8, from pneumonia, aged 55.

Lewis E. Higbee, M.D. Universit [illegible] Ann Arbor, 1875; local surgeon to the C [illegible] Trunk Railroad; died at his home in P [illegible] rom cerebral hemorrhage. December 9, aged 62.

Miner Wadsworth, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1882; a member of the Ohio State

Medical Association; died at his home in Hoytville, December 8, from kidney disease, aged 54.

Samuel M. Crume, M.D. University of Kentucky, Louisville, 1906; formerly of Willisburg, Ky.; a member of the American Medical Association; died suddenly at his home in Tucumcari, N. M., December 8.

Ralph Erwin, M.D. University of Vermont, Burlington, 1861; a surgeon in the Army during the Civil War; fell down stairs at his home in Malone, N. Y., December 9, and was instantly killed, aged 70.

Oscar Kirchgessner, M.D. Michigan College of Medicine and Surgery, Detroit, 1905; of Detroit; assistant to the coroner of Wayne county; died in Denver, Colo., December 8, from tuberculosis, aged 29.

William D. Hopkins, M.D. University of Pennsylvania, Philadelphia, 1850; of Rockingham, Va.; died at the Western State Hospital, Staunton, November 24, from senile gangrene, aged 85.

William A. Tope, M.D. Rush Medical College, Chicago, 1887; of Downers Grove, Ill.; died December 11, in Albuquerque, N. M., where he had gone in the hope of bettering his health, aged 49.

George Franklin Peters, M.D. Northwestern Medical College, St. Joseph, 1893; for a year assistant city physician of St. Joseph, Mo.; died at his home in King City, Mo., December 4, aged 38.

George W. Benton, M.D. Louisville (Ky.) Medical College, 1878; a member of the State Medical Association of Texas; died at his home in Woodbury, December 12, from pneumonia, aged 59.

F. Julius Heintz (license, La.), coroner of St. Tammany Parish for fifteen years, and mayor of Avita Springs ever since its incorporation; died at his home November 20, aged 53.

David M. Provence, M.D. University of Virginia, Charlottesville, 1890; of Rutherford College, N. C.; died near Wilksburg, S. C., November 29, from tuberculosis, aged 40.

Charles Sumner Haines, M.D. University of Vermont, Burlington, 1879; a member of the Medical Society of the State of New York; died at his home in Redford, November 24

Robert J. Caldwell, M.D. Medical College of Georgia, Augusta, 1871; a Confederate veteran; died at his home in Mooresville, N. C., December 7, from pneumonia, aged 68.

John W. Drewry, M.D. Medical College of Virginia, Richmond, 1872; a member of the Medical Society of Virginia; died at his home in Boykins, November 14, aged 57.

John A. Knipple (license, Blair Co., Pa., 1888), formerly of Butlersville, Pa.; died at the home of his daughter in Blue Knob, Pa., November 19, from pneumonia, aged 68.

Eber S. Carlisle, M.D. University of Buffalo, N. Y., 1868; a member of the Medical Society of the State of California; died at his home in Los Angeles, December 8, aged 65.

Andrew J. Wallace, M.D. Starling Medical College, Columbus, Ohio, 1869; of Decatur, Ill.; died in St. Mary's Hospital, East St. Louis, October 6, from nephritis, aged 67.

Henry C. Winger (examination, Pennsylvania, 1896); for more than fifty years a practitioner of Harrisburg, Pa.; died at his home in that city, December 5, aged 72.

Donald Martin Fraser, M.D. McGill University, Montreal, 1869; local surgeon for the Grand Trunk System; died at his home in Stratford, Ont., December 9, aged 62.

Edward C. Prigg, M.D. Physio-Medical College, Cincinnati, 1842; died at his home near Middletown, Ind., April 16, as the result of a fracture of the hip, aged 82.

Michael A. Kadien, M.D. Bellevue Hospital Medical College, 1891; died suddenly from myocarditis at his home in New York City, December 14, aged 49.

Henry J. Patten, M.D. Eclectic Medical Institute, Cincinnati, 1883; died at the home of his daughter in Chicago, December 15, aged 69.

Wiliam C. Hoover, M.D. Vanderbilt University, Nashville, Tenn., 1879; died at his home in Bellbuckle, Tenn., December 10, from paralysis.

F. L. Palardy, M.D. Medical Department of Victoria College, Toronto, 1867; died at his home in Montreal, May 27, aged 62.

Marion Goss, M.D. University of Virginia, Charlottesville, 1870; died at his home in Rockville, Ind., December 13, aged 62.

John Davis, M.D. Medical College of Philadelphia, 1862; died at his home in Pottstown, Pa., December 11, aged 76.

Jerome L. Love, M.D. St. Louis Medical College, 1877; died at his home in Whiting, Kan., December 9, aged 69.

John M. Davis (years of practice, Ill., 1896); died at his home in Hamilton, Ill., December 6, aged 75.

Medicolegal

Waiver of Privilege in One Case Applies to Another.

The Court of Appeals of New York says that the question presented in the criminal prosecution for perjury of People vs. Bloom was whether the defendant, by failing to object to the testimony of certain physicians on the trial of a civil action for damages against a street railway company waived his right to object to their testimony on the trial of the criminal action. The defendant did not cause or procure the evidence of the physicians to be admitted when the civil action was tried, but he made no attempt to prevent its admission, although it was within his power to keep it out, or to avail himself of the privilege conferred by the statute. He did not waive by acting, but by failing to act. Whether his failure to object was owing to advertence, or policy, or to some other reason, did not appear, and was not here material. It was conceded that he waived the benefit of Section 834 of the New York Code of Civil Procedure, so far as the trial of the civil action was concerned, and the real question was, what effect did that waiver have on subsequent trials, civil or criminal?

The court holds that the waiver in the first case applied to the second. It says that the object of the statute, as this court has uniformly held, "is to prevent the disclosure of delicate and confidential matters, which might humiliate the patient in his lifetime and disgrace his memory when dead, so as to enable him to consult a physician in safety, knowing that his lips would be sealed by the law until he himself removed the seal." Section 836, in its present form, expressly refers to "confidential communications, and such facts as would tend to disgrace the memory of the patient."

Whether the waiver is by the affirmative action of the patient in calling forth the privileged testimony, or by his negative action in not preventing the other party from calling it forth, the logical effect is to deprive the statute of all further power of protection, because there is nothing left to protect against. The section no longer applies when the information that the statute would have kept secret, if the patient had so elected, has been made known in a judicial proceeding with his consent.

After intentionally permitting its publication to the world by the patient himeslf, on one trial, it would seem almost grotesque to sustain an objection made on a later trial that the evidence is privileged from disclosure, because it might tend to humiliate or disgrace. There can be no disclosure of that which is already known, for when a secret is out, it is out for all time, and can not be caught again like a bird, and put back in its cage.

The disgrace and humilation were caused by the first trial, not by the second.

The legislature did not intend to continue the privilege when there was no reason for its continuance, and it would simply be an obstruction to public justice.

Monthly Sickness as Evidence of Age.

The Court of Appeals of Kentucky holds, Howerton vs. Commonwealth, where the party appealing had been convicted of carnally knowing a female under the age of 16 years, that it was error to exclude, as incompetent, testimony offered by the defendant tending to show that the monthly sickness of the prosecutrix had regularly occurred and existed for a period of five years preceding his alleged abuse of her. The court thinks it was competent on the question of her age; for, if it continued more than five years before the commission of the crime, it would tend to show that she was over 16 years of age at that time. While by no means convincing, it would, in view of the conflicting evidence as to her age, have been a circumstance to the benefit of which the defendant was entitled, as it was important for him to show that at the time of his having carnal knowledge of her, if the jury believed he did so, the prosecutrix was over 16 years of age, and therefore of sufficient age to consent.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

7 Correct Treatment of Fracture of the Clavicle. R. Bellantoni, New York.
8 *New Operation for Hemorrhoids. C. W. Heitzmann, Kansas City, Mo.

1. Abstracted in The Journal, Nov. 21, 1908, p. 1813.

2. **Cow's Milk.**—Gorton discusses the milk problem and points out, among other things, the fact that cowdung is contained in almost all milk, and that the greatest danger from the tuberculous cow lies in the infectious character of the manure. He discusses the question of the two types of bacilli and says that there can no longer be any doubt that the bovine type of tubercle bacillus can and does infect man. The great danger of contaminated dairy products is for children, and he believes that few, if any, adults acquire tuberculosis by their ingestion. To rid milk of this menace we must either free our dairies of tuberculosis or so treat all infected milk that the contained tubercle bacilli are destroyed. He discusses both these methods, and holds that the advantages of treating contaminated milk in such a way as to insure the destruction of the bacillus are more than counterbalanced by inherent objections to the method. He particularly discusses pasteurization, pointing out that there is some evidence that it is a cause of rickets and scurvy. While general pasteurization is the easiest way of preventing the presence of live tubercle bacilli in market milk, it is the most slovenly and unbusinesslike method. It is curative when our efforts should be preventive. General pasteurization of milk, whether performed by dealers or municipal bureaus, robs the producer of all incentive to produce clean milk low in bacteria, and puts a premium on filth and disease in milk. Pasteurization of milk used for infant feeding during hot weather is often desirable, but the greatest purpose served by so treating it is the prevention of gastrointestinal disorders, not tuberculosis. Summer pasteurization of milk alone should be countenanced, and this does not protect the infant from the tubercle bacillus except for a small part of the year. General and constant pasteurization of market milk should not be permitted to displace strenuous and proper efforts to rid our dairies of tuberculosis.

3. **Tuberculosis in Tenements.**—Taylor discusses the condition of the tenement dwellers in reference to tuberculosis and suggests that with all other available measures—sanatoria, day camps, etc., there must remain the necessity of doing as much as possible to improve the condition of their squalid quarters, by lessons in sanitation. It is surprising how much can be done in 24 hours under one pretext or another, to transform a dingy corner into a habitat of cheer. It is well known, says the author, that workers in lime escape consumption, or even if it is present it becomes arrested. He therefore recommends whitewashing walls, ceilings and cellars. The family may get a breath of outside air while a sulphur candle kills the germs. The cult of fresh air and scrubbing, etc., can be promoted, and many ways will suggest themselves to a tactful physician, for beneficial yet inoffensive changes. But this is a physician's privilege, not to be shared by any other person, from whom it will be often resented.

4. **Dementia Præcox.**—Karpas concludes the article begun in the preceding issue. He discusses the etiologic relationship of dementia præcox to heredity, autointoxication, seasons, age, nationality, psychotic traits, education, sociologic conditions and occupation, sex, previous diseases, masturbation, civil condition, pregnancy, childbirth, etc., trauma, alcohol, prisons, infectious diseases and operations, and emotional influences. He does not offer any conclusive deductions, but accentuates the fact that heredity and constitutional makeup are important etiologic factors.

8. **Hemorrhoids.**—Heitzmann describes an operation which consists essentially in an incision carried in the long access of the bowel over each hemorrhoid without wounding the blood vessel. The vessels are then exposed and liberated and a small catgut ligature is applied above and below. The vessels are extirpated with scissors or knife, and if necessary the mucous membrane is closed with catgut. The only dressing is a sterile pad over the anus. The operation is not applicable to friable or capillary hemorrhoids or to the so-called connective tissues or cutaneous forms. There is said to be little hemorrhage and little danger of secondary hemorrhage. It is practically painless.

Medical Record, New York.

December 12.

9 *Physiologic Significance of That First Lesson. S. Smith, New York.
10 Statistical Study of Renal Colic and Hepatic Colic. B. Symonds, New York.
11 Ileocolic Circle. B. Robinson, Chicago.
12 *Tuberculosis Problem in the Philippines and the Elimination of Intestinal Parasites as the First Step in Its Solution. V. G. Heiser, Public Health and Marine-Hospital Service.
13 *Neuroses of the Nose. C. P. Grayson, Philadelphia.
14 *Treatment of Amebic Dysentery as Conducted on the Isthmus of Panama. W. E. Deeks, Panama.

9. **The First Lesson.**—Smith describes the mode of education adopted by Dr. Wilbur at the Custodial Asylum for the Feeble-Minded, and discusses the physiologic course of impressions. The cell is the medium of the highest psychic functions. While its intimate texture is inherited, it may be modified by exercise, nutrition and environment. The brain cells may be awakened and developed, and the brain of the feeble-minded class thus educated into intellectuality. The organization of the service of such institutions to individualize study and record, an exhaustive first examination revealing all faults of nutrition and assimilation, family organization of the institution, and special training of the attendants under the personal supervision of the officers, are insisted on. He concludes that there is a far more hopeful outlook nowadays for the feeble-minded, the insane and the criminal. Instead of reasoning backward from the effect to cause and thus reaching a vague and indefinite conclusion, skilled and expert anatomists and physiologists, inspired by the scientific spirit of the age, are gradually penetrating and unveiling the mysteries of the brain, the center and source of all mental activities, thus laying the foundations of a true science of psychology.

12. **Intestinal Parasites and Tuberculosis.**—On the basis of experience in the Philippines, Heiser produces facts which he believes warrant the assertion that in tropical countries where tuberculosis and hookworm diseases are coexistent, the elimination of the hookworm will produce better results in diminishing the mortality from tuberculosis than any measure that has as yet been tried on a large scale. At the same time the general mortality can be markedly reduced.

13. **Neuroses of the Nose.**—Grayson discusses hay fever. He considers the search for a specific foredoomed to failure. Nothing short of a drastic and radical reform of each patient's personal hygiene can effect and maintain the normality of the body tissues and secretions. It is his belief that if a man takes care of his muscles, with all that this implies, his nerves and vasomotor centers will take care of themselves. He next discusses rhinorrhea spasmodica, or paroxysmal sneezing, which

seems to be hay fever minus the latter's idiosyncrasy to external irritants; the internal irritants and the secondary nervous element being doubtless precisely the same in the two cases. He concludes with a discussion of what he terms "honeymoon rhinitis," a neurosis having its origin in disordered sexual functions.

14. **Amebic Dysentery.**—Deeks describes the variety of treatments that have been tried on the Isthmus, which have proved of little or no value. He considers it bad practice to give irritating injections, such as quinin or thymol; opiates are equally bad. The present method, which has given brilliant results with rarely a fatality, consists in what might be called the rest supportive treatment. The patient is put to bed, absolute rest is enjoined, a purely milk diet is administered, and when great tenesmus is present warm saline irrigations are given two or three times daily. A preliminary dose of castor oil is usually advisable. The only internal medication which is given is the subnitrate of bismuth, which is administered in somewhat heroic doses, from a dram to a dram and a half every three hours. In the milder cases improvement begins in from 3 to 5 days; in the severer cases in from 10 to 14 days. The stools then lessen in number and become formed, and in a comparatively short time—from one to three weeks—from 12 to 24 hours are passed without a movement. The diet is then gradually increased and the bismuth lessened in dosage. Usually the proteids, meat and eggs, are the last to be added to the full dietary. In from one to four weeks, depending on the severity of the case, the patients are perfectly well. It is then well to give tonics and advise change of air.

15 *Method of Administering Antimeningitis Serum. C. H. Dunn, Boston.
16 Carcinoma of the Appendix, Probably Primary, in a Child Nine Years and One Month of Age. H. F. Day and L. J. Rhea, Boston.
17 Electrotherapeutics in Tuberculosis. J. F. Wallis, Norristown, Pa.
18 *Certain Evil Tendencies in Medicine and Surgery (continued). M. H. Richardson, Boston.
19 *Bursitis Subacromialis, or Periarthritis of the Shoulder-Joint (Subdeltoid Bursitis.) (Concluded.). E. A. Codman, Boston.

15. **Antimeningitis Serum.**—Dunn, at the suggestion of Flexner, lays great emphasis on the use of the subdural method of injection only, and that in suitable doses at proper intervals. He summarizes as follows the proper method of using antimeningitis serum:

1. Perform lumbar puncture, prepared to give the serum as soon as *meningitis is suspected.* If the fluid is cloudy, give the first full dose of serum at once, without waiting for the bacterial examination, although further doses are only to be given in case the *Diplococcus intracellularis* is found in the cerebrospinal fluid. The serum is of no value in other forms of meningitis.
2. At every dose give as much as possible. Always withdraw as much cerebrospinal fluid as possible. Give 30 c.c. in all cases in which the amount of fluid is withdrawn is 30 c.c. or less, unless a distinctly abnormal sense of resistance is encountered after as much has been injected as has been withdrawn. In all cases *in which the amount of fluid is more than 30 c.c.,* give as much serum as the quantity withdrawn. In very severe or fulminating cases, in which the amount withdrawn is between 30 c.c. and 45 c.c., *give 45 c.c. unless abnormal resistance is* encountered.
3. In very severe or fulminating cases, repeat within 24 hours as soon as the patient begins to get worse again, or *at 12-hour* intervals.
4. In average cases, repeat daily, until four full doses have been given in all cases.
5. If diplococci persist after four full doses have been given, *continue* the injections until they [illegible]
6. If subjective symptoms, any [illegible] ·ntal condition or fever persist after diploc [illegible] *or after* four full *doses have* been given without progressive improvement, wait four days if the condition of the patient is stationary. At the end of four days, or at any time if the patient's condition is getting worse, repeat the treatment with four daily full doses, and continue as if this were the original attack.
7. When a relapse occurs, either by reappearance of diplococci in the cerebrospinal *fluid or by a reappearance* of symptoms, give four daily full doses and continue treatment as if this were the original attack.
8. Treatment along these lines should be *continued until the* patient is symptom-free, without diplococci in the fluid, or until the chronic stage is established.
9. In the chronic stage watch *for* possible reappearance of diplococci by doing occasional lumbar puncture. If diplococci *reappear,* resume treatment with the serum as outlined above. In chronic cases with excessive cerebrospinal fluid under *marked* pressure, try daily lumbar puncture *without* the injection of serum.

18. **Evil Tendencies in Medicine and Surgery.**—Richardson continues his remarks on this subject with a series of instances illustrating points bearing on this matter. In one instance he had at the very operating table to rely on the history to decide on methods of operating, even when the lesion was in full view and in his very finger. He emphasizes the importance of the education of the finger tips as the one thing indispensable to the practitioner, and considers good the tendency backward to the old-fashioned methods of diagnosis. All modern methods should be studied and applied, but not under any glamour or to the neglect of the others. A diagnosis of little cause for operation must be severely questioned when the alternative is a great cause, e. g., the diagnosis of benign mammary tumor must be severely questioned because its alternative is malignant mammary tumor; the same with acute indigestion, whose alternatives include acute appendicitis, perforated gastric ulcer or gallstones.

19. **Bursitis Subacromialis.**—Codman concludes his article as follows:

1. The subacromial bursa and the supraspinatus muscle are of essential value in abduction of the arm.
2. Lesions of the subacromial bursa and of the tendon of the supraspinatus *are the common causes of stiff and painful shoulders.*
3. Many cases which pass under the diagnoses of contusion of the shoulder, neuritis, periarthritis, circumflex paralysis and muscular rheumatism are in reality due to lesions of these structures.
4. The final prognosis of these cases is good, but when pain is severe, or disability is great, relief may be obtained by a simple operation of *little* danger.

9 Etiology of Beriberi and the Presence of Arsin in Rice. C. N. Saldanha.

1. **Inaugural Symptoms.**—Moynihan points out that the classical descriptions of the pathology of disease are mainly built on those later clinical symptoms that could be subsequently correlated with postmortem appearances. At present, the surgeon, owing to the frequency of internal operations, has the opportunity of studying, not only those parts that call for operative intervention, but all other parts laid bare through the same incision. If a morbid process in its *earliest stage be found* in other parts, the patient's story of his sufferings may be retold and cross examination conducted thereon as soon as recovery from the operation is complete. In this way much of the text-book *symptomatology* can be revised. Moynihan insists on the importance of the "anamnesis," which word, he holds, should come into more general adoption, being strictly limited in *meaning to* its proper sense, namely, the calling again to *mind* of incidents in the past, the recollection of occurrences, almost or *entirely* forgotten until thought is concentrated on them. The study of inaugural symptoms will be of the greatest service in abdominal diseases. With regard to gastric or duodenal ulcer, Moynihan says that the sudden onset of an acute *intolerable* pain that does not abate, rigidity of all the abdominal muscles, light and shallow breathing, with an inspiratory *phase* that often ends abruptly in a "catch," together with the intensely anxious expression which the face always wears, are *ample*

warrant for a diagnosis of a perforation. A previous history of indigestion is rarely if ever lacking. A rapid pulse, vomiting, and abdominal distension are to be looked for among the inaugural symptoms. He discusses also the inaugural symptoms of gallstone disease and of carcinoma of the stomach. In cancer of the large intestine the first sign, he thinks, is the insidious onset of intestinal irregularity, now slight constipation, now slight diarrhea. Another point is a slight transient spasm in a part of the large intestine. The patient tells of a feeling of "gripping" in a certain limited area of the abdomen and points always to the same spot. Borborygmi are heard synchronizing with the spasmodic pain. In regard to appendicitis, he has verified the point emphasized by Murphy, that pain is the inaugural symptom and that if other symptoms apear first the diagnosis must be regarded with suspicion. Of the association of pancreatitis with gallstone, he thinks the better view may be that both gallstones and pancreatitis are themselves the result of an infection of the bile as it descends from the liver. He discusses the relation of diabetes to the pancreas, and in conclusion points out that it is to the cooperation of the general practitioner with the surgeon that help in this research must be looked for.

2. **Rheumatic Serous Inflammation.**—Smith points out that the rheumatic origin of serous inflammation of the pericardium is generally admitted; yet a similar source for other serous inflammations is less willingly conceded. He briefly reports two cases; the first, of a localized peritonitis, in which the illness had in all respects the features of an ordinary attack of inflammation of the appendix. The inflammation very rapidly subsided under sodium salicylate. He believes rheumatic appendicitis to be a common complaint. The second case was one of general peritonitis of most virulent character, the patient being considered moribund. Yet the disease changed its whole character within twenty-four hours after the administration of sodium salicylate every three hours, and at the end of forty-eight hours the patient was out of danger. Smith considers it advisable in all cases of appendicitis to begin treatment with a few substantial doses of sodium salicylate, for the rheumatic element can not be excluded until the result of treatment by this remedy has been ascertained.

Lancet, London.

November 28.

10 *Pathology and Treatment of Diabetes Mellitus Viewed By the Light of Present Day Knowledge. F. W. Pavy.
11 *"Effective Periods" of Typhoid Bacilli Carriers. D. S. Davies and I. W. Hall.
12 The Common Cold: Its Pathology and Treatment. R. W. Allen.
13 Case of Lichen Plano-Pilaris in Which the Spinous Element Predominated. A. F. Savill.
14 Sterilization of Potable Waters by Calcium Hypochlorite. J. C. Thresh.

10. **Diabetes.**—Pavy's considerations lead to the view that the products of digestion become assimilated at the seat of absorption. By this assimilation they become rebuilt, before reaching the circulation, into molecules of sufficient size to be precluded from flowing off with the urine in their passage through the kidney, in contradistinction to what is known to occur with the digestion products themselves when circumstances exist to lead to their demonstrable presence in the blood. All experimental work affords testimony of sugar standing in the same position as salines and urea in relation to the property of passing off with the urine. Impermeability of the kidney to sugar is, as he has before stated, a pure fiction raised on the false conception of healthy urine being free from sugar. The real circumstances are that the urine constitutes an indicator of the state of the blood with respect to sugar, no matter whether the amount existing be large or small, and thence it may be concluded that if sugar were reaching the circulation, as is contended for under the glycogenic theory, it could not escape being rendered evident by the urine, just as indeed happens in connection with diabetes.

11. **Typhoid Bacilli Carriers.**—Davies and Hall examine two of their typhoid carriers and the summaries of the cases reported elsewhere. The points shown by their studies are that every carrier appears to have periods of maximum and minimum danger, and that a knowledge of these should be of great value in prophylaxis. It is noted that there is an almost uniform absence of "effectiveness" of the carrier during the early months of the year. The authors suggest the following studies with reference to the period of ineffectivity. Is this periodical failure of the carrier to become "effective" simply coincidence, or shall we find it appearing uniformly when a large number of cases are available for reference? Has it anything to do with periodicity in the virulence of the bacillus? Does the organism live a "hibernant" existence in the intrahepatic and extrahepatic biliary passages during these months, and become actively parasitic on reawakening for the remaining months of the year? Has this "period of effectiveness" anything to do with the type of food taken, or with the general tissue metabolism, or with the heat regulation apparatus? Does this "seasonal effectivity" offer any explanation of the "waves" of endemic enteric fever, the May revival starting the supply of fresh infections, which subsequently develop by extension into the autumnal burst? There are certain indications which might be followed until more knowledge points to other pathways:

1. *Systematic examination of the feces of convalescents or suspected carriers.*—These examinations must be made day by day and extend over long periods.
2. *Urine.*—The marked excretion of the typhoid bacilli during the later weeks of the acute attack does not appear to have its parallel in the carrier.
3. *Blood.*—The agglutinating properties of the blood may afford evidence of the "effectiveness" of the carrier.
4. *Temperature and pulse.*
5. *Hands.*—It may be worth while to make bacteriologic examination of the nails and fingers.
6. *Immunity.*—Determinations of immunity can only be carried out in bacteriologic laboratories, but it may be necessary to resort to them in some instances. Speaking generally, the immunity of the typhoid carrier must vary considerably from time to time. It lies near to hand to think of raising the immunity of the carrier by injections of vaccines.

Obstétrique, Paris.

16*Elongation of Cervix Complicating Delivery. (De l'allongement œdémateux, polypiforme, unilabial du col complication de l'accouchement.) J. Rouvier.

No. 5, pp. 417-560.

17 *Treatment of Puerperal Infection by Fixation Abscesses. A. Boissard.
18 *Indications and Prognosis of Pubiotomy. (Hebotomie.) C. Jeannin and V. Cathala.
19 *Treatment of Tubal Pregnancy After Rupture or Abortion. (Grossesse extra-utérine.) H. Treub.

16. **Elongation of the Cervix Complicating Delivery.**—Rouvier has found in the literature twenty cases, in addition to one personally observed, in which the cervix became elongated in the form of a polyp, and interfered with delivery. In all but one of the cases on record the anterior lip was the seat of the lesion. It is the result of some intense mechanical disturbance in the local circulation and may subside after childbirth. The elongation may be mistaken for a cystocele or rectocele or a vascular or fibrous polyp or other tumor, and thrombosis or a hematoma may be a serious complication. Spontaneous subsidence of the tumor during labor is the exception, and expectant treatment is justified only in the mildest forms and in the early stage. After rupture of the fetal membranes, the evacuation of the uterus should be accelerated and the swollen lip pushed back. Gentle compression may aid in the absorption of the fluid content. Scarifications may open a way to infection, but they might be useful in some cases. Extreme care is necessary if forceps are used.

17. **Treatment of Puerperal Infection by Fixation Abscesses.**—Boissard says that the decline of serotherapy in puerperal infection is bringing the Fochier fixation abscesses into vogue again. He has had favorable experience with them, and urges their more general adoption in puerperal infection if the toxic phenomena do not rapidly wane, but are becoming accentuated, rebellious to ordinary measures. No one will ever regret having made them too early in these circumstances. He takes up a fold of the skin on the thigh or side of the chest, inserts the needle into the subcutaneous tissue, and injects at least 3 c.c., preferably 4 or 5, of oil of turpentine. One of his patients received by mistake 20 c.c., and the local reaction was intense; the entire limb swelled, but there were no complications and the patient recovered. There are no general phenomena after the injection of turpentine; the only reaction is the pain at the point of injection. By the second day the abscess begins

to show and it reaches its full development by the sixth day and can be incised on the seventh or eighth. After the pocket is empty it is rinsed out with peroxid of hydrogen or boiled water. Thirteen cases are described, all of extremely severe puerperal infection, and the results observed were far better than with any other mode of treatment in his experience.

18. **Prognosis and Indications for Pubiotomy.**—Jeannin and Cathala have performed pubiotomy in 3 cases and review the whole field of these operations to date in 21 clinics. The maternal mortality ranges from zero to 11 per cent., and averages about 6 per cent., although the fatal outcome in some of these cases should not be attributed to the operation. They compare the outcome of pubiotomy, symphyseotomy and conservative Cesarean section, tabulating 39 cases of the latter, with only one fatality, and this the result of a burn. They regard pubiotomy as much more satisfactory than symphyseotomy, and prefer the open to the subcutaneous technic for pubiotomy. With full dilatation and normal conditions, Cesarean section is preferable, but in case of signs of infection pubiotomy with drainage is preferable.

19. **Treatment of Tubal Pregnancy After Rupture or Abortion.**—Treub has been collecting statistics in regard to operative treatment of tubal abortion in Holland, and has collected 331 cases with a total mortality of 12.6 per cent. In 10 cases the women succumbed in less than two hours; there were only 5 cases in which death occurred from a second hemorrhage. These figures include 170 severe cases. In 29 the operation was done within 48 hours, and 31 per cent. of the patients died. Among the 141 women treated by a deferred operation, the mortality was only 9.25 per cent. In 2 of the fatal cases the operation was done in the 24 hours following the rupture. Taking into consideration the fact that death rarely occurs within 24 hours, he thinks that the rapid operation was probably responsible for the fatal outcome. He then describes his personal experience, which includes 151 cases. In 27 the condition was serious, and there was one death from repeated hemorrhage. Among the others he regarded laparotomy as indicated in only 2 cases and this not until after recurring hemorrhage. In 20 cases he evacuated the hematocele through the vagina, and 4 of the women recovered without any operation. Among the 124 other cases, which he classifies as not serious, a secondary operation was performed in all but 24. Laparotomy was done in only 16 cases, and one of the women succumbed to peritonitis from lack of trained nursing. In 2 cases the laparotomy was required for ileus: a loop of the intestine had become adherent to the walls of the hematocele. The operation saved only one of these women. In 7 other cases the laparotomy was indicated by the uncertainty in the diagnosis, and once to arrest hemorrhage not amenable to control by the vaginal incision. The other 84 women were all treated by secondary colpotomy, and all recovered except one with pre-existing peritonitis. His total mortality was thus 2.6 per cent. of the 151 cases. He adds in conclusion that whoever originated the term, "the flooding of the peritoneum from the tubal rupture," must have a number of superfluous operations and operative fatalities on his conscience. The hematocele forms only gradually; the vague but suggestive term, "flooding the peritoneum," is harmful in two ways: It is a scarecrow for those who are not surgeons, and an excuse for the operators. The truth is that the rupture of the extrauterine sac only exceptionally proves fatal at once. These exceptional cases are those in which the alarming symptoms increase during several hours, notwithstanding suitable treatment, and those in which the hemorrhage recurs in a serious form. These extremely rare cases alone justify primary and rapid intervention. In all other cases treatment should be negative. No attempt should be made to obtain a detailed diagnosis, no examination by the vagina to see if there is a hematocele; it does not form until later, and manipulations do no good, but may increase the chances for hemorrhage. Absolute repose, ice to the abdomen, an opiate when the shock is over: this is all for the first days. Then, instead of the ice pack, warm fomentations to the abdomen, supplemented a few days later by hot vaginal douches. This treatment should be kept up for four or five weeks unless signs of suppuration in the hematocele indicate a secondary operation. If the reabsorption of the blood drags too long, colpotomy may be done after five or six weeks; it is then simple and harmless.

22 *Secondary Cancer Septicemia. Le Noir and Courcoux.

22. **Secondary Cancer Septicemia.**—Le Noir describes a case in which a young man entered the hospital on account of general debility with intense anemia and pain in the lumbar region. Three years before he had had right hemiplegia with aphasia, all subsiding in the course of a year. During the last six months pain in the right flank, spreading to the lumbar region, was accompanied by intense anemia. Autopsy revealed an unsuspected cancer at the pylorus. No embolism could be detected in the primary tumor, but an adjoining gland was evidently the source of the rapidly fatal septicemia. The embolism followed the ramifications of the portal vein.

23 *New Sign of Functional Paresis of the Extremities. (Valeur du phénomène de "l'opposition complémentaire" comme moyen de diagnostic entre les hémiplégies organiques et les hémiplégies fonctionnelles.) J. Lhermitte.

23. **New Sign of Functional Paresis of the Lower Extremities.**—The sign described by C. F. Hoover in The Journal, Aug. 29, 1908, page 747, has been tested by Lhermitte in 14 cases of organic hemiplegia at the Salpêtrière, the findings confirming Hoover's assertions in regard to the diagnostic importance of the "complemental opposition" in genuine paresis of the lower extremity: The heel of the other foot digs into the couch as the leg is voluntarily lifted. In another case reported by Lhermitte in which the symptoms all point strongly to hysteria, the complemental opposition is as marked as in a case of genuine organic hemiplegia. The patient is a young married woman from the rural districts, never in contact with hysterics and without pathologic antecedents. Sudden pain in the left hand was the first symptom, followed by the gradual development of multiple contractures with reflex atrophy of the quadriceps. The Hoover sign is particularly pronounced in this puzzling case. In another case a woman of 54 presented typical major attacks of hysteria. During hypnotic sleep Lhermitte induced by suggestion complete right hemiplegia. Lying on a couch in the dorsal position the patient could easily lift the left leg, but all movement of the right leg was impossible, although traces of the complemental opposition could be felt in the muscles of the paralyzed leg as the left was lifted. But when the paralyzed leg was lifted there was not a trace of the complemental opposition in the other leg. The absence of the complemental opposition in this case harmonizes with the assumption of the functional nature of hysteric hemiplegia. It further confirms Babinski's statements in regard to the identity of hysteric paralysis and the paralysis experimentally produced in persons influenced by suggestion in hypnosis. The sign thus not only serves to differentiate malingering and functional paresis, but it also throws light on the mechanism of hysteric paralyses. The fact that the muscular effort and contraction of the complemental opposition can be distinctly perceived by the hand, placed under the heel, even when the limb is utterly incapable of volitional movements, shows, he thinks, that the subconscious movements are retained unimpaired in hysteria, while the movements which depend directly on the will are suspended. The mechanism of hysteric paralysis is thus seen to be of an entirely different nature from that of organic paralysis. The hysteric paralysis is not the consequence of a functional disorder limited to a given anatomic system, but is evidently the result of disturbance in the psychic functions, an essentially mental process. Lhermitte explains the sign as due to the natural subconscious effort to maintain static symmetry in the pelvis as the leg is lifted. The digging of the other heel into the couch does not help to lift the leg, but it helps to maintain this static balance.

GENERAL INDEX

All *reading matter* in The Journal from July to December, 1908, inclusive, is indexed here (For Current Medical Literature Index see pages 2271 to 2320) "Deaths" "Book Notices" and "Society Proceedings" are indexed under those titles at the ends of the letters "D," "B" and "S" Matter pertaining to the Association is under "American Medical Association" With the above exceptions, all matter is indexed under the most important word of the heading that was used in The Journal, and also under the subject heading For instance, abscess of brain will be found indexed under "abscess" as well as under "brain" Such titles as "ocular manifestations, etc," have been indexed under "eye" Cross references have been made wherever this was possible It is also well to remember that, in looking up a certain subject, related words should be consulted, for example, testes, testicle, skull, cranium, bowel, intestines The letters used to explain in which department the matter indexed appeared are as follows "E" editorial, "O" original article, "C" correspondence, and "ab" denotes an abstract of an article that has appeared in full elsewhere *Names of authors* of original articles appearing in The Journal are not given in this index, but are included in the Index of Authors.
